BGG RESOLUTIONS VIA CONFIGURATION SPACES

BY Michael Falk, Vadim Schechtman & Alexander Varchenko

To the memory of I.M. Gelfand, on the occasion of his centenary (1913–2013)

Abstract. — We study the blow-ups of configuration spaces. These spaces have a structure of what we call an Orlik–Solomon manifold; it allows us to compute the intersection cohomology of certain flat connections with logarithmic singularities using some Aomoto type complexes of logarithmic forms. Using this construction we realize geometrically the $\mathfrak{sl}_2$ Bernstein–Gelfand–Gelfand resolution as an Aomoto complex.

Résumé (Résolutions BGG via les espaces de configurations). — Nous étudions les éclatements d’espaces de configuration. Ces espaces ont une structure de variété que nous appelons d’Orlik-Solomon ; elle permet de calculer la cohomologie d’intersection de certaines connexions plates avec singularités logarithmiques à l’aide de complexes de formes logarithmiques du type d’Aomoto. En utilisant cette construction, nous donnons une réalisation géométrique de la résolution de Bernstein–Gelfand–Gelfand pour $\mathfrak{sl}_2$ comme un complexe d’Aomoto.

1. Introduction

Let us discuss briefly some general perspective and motivation.

Localization of \( \mathfrak{g} \)-modules: two patterns

(a) Localization on the flag space. — Let \( \mathfrak{g} \) be a complex semisimple Lie algebra, \( \mathfrak{h} \subset \mathfrak{g} \) a Cartan subalgebra whence the root system \( R \subset \mathfrak{h}^* \); fix a base of simple roots \( \Delta \subset R \) whence a decomposition \( \mathfrak{g} = \mathfrak{n}_- \oplus \mathfrak{h} \oplus \mathfrak{n}_+ \). The classical Bernstein–Gelfand–Gelfand resolution is the left resolution of a simple finite dimensional \( \mathfrak{g} \)-module \( L_\chi \) of highest weight \( \chi - \rho \) (where \( \rho \) is the half-sum of the positive roots) of the form

\[
0 \rightarrow C_n \rightarrow \ldots \rightarrow C_0 \rightarrow L_\chi \rightarrow 0,
\]

where

\[
C_i = \bigoplus_{w \in W_i} M_{w\chi},
\]

cf. [BGG75]. Here \( M_\lambda \) denotes the Verma module of the highest weight \( \lambda - \rho \), and \( W_i \subset W \) is the set of elements of the Weyl group of length \( i \).

We can pass to contragredient duals and use the isomorphism \( L_\chi = L^*_\chi \) given by the Shapovalov form to get a right resolution

\[
0 \rightarrow L_\chi \rightarrow C^*_0 \rightarrow \ldots \rightarrow C^*_n \rightarrow 0,
\]

where

\[
C^*_i = \bigoplus_{w \in W_i} M^*_{w\chi}.
\]

A geometric explanation of the last complex was given by Kempf, [Kem78], who interpreted (1.2) as a Cousin complex connected with the filtration of the flag space \( G/B \) by unions of Schubert cells (\( G \) being a semisimple group with Lie algebra \( \mathfrak{g} \) and \( B \subset G \) the Borel subgroup with \( \text{Lie}(B) = \mathfrak{b} := \mathfrak{h} \oplus \mathfrak{n}_+ \)). Here the \( i \)-th term is interpreted as a relative cohomology space with support in the union of Schubert cells of codimension \( i \). This geometric picture is a part of Beilinson–Bernstein theory which says that some reasonable category of \( \mathfrak{g} \)-modules is equivalent to a category of (twisted) \( \mathcal{D} \)-modules over \( G/B \), [BB81].

(b) Localization on configuration spaces. — In a different direction, contragredient Verma modules and irreducible representations have been realized in [SV91] in certain spaces of logarithmic differential forms on configuration spaces. This may be upgraded to an equivalence between some category of \( \mathfrak{g} \)-modules and some category of \( \mathcal{D} \)-modules over configuration spaces, cf. [KS97, BFS98, KV06].

Blow-ups and their “Schubert” stratifications. — In this note we propose a construction which provides a geometric interpretation of the resolutions similar to the BGG resolution in (1.2). The main new idea is to use the blow-ups of hyperplane arrangements (in our case – the configuration arrangements) studied in [ESV92, STV95, BG92, Var95, DCP95]. We define some natural stratifications on such blow-ups which play the role of the Schubert stratification on \( G/B \). On each stratum we consider the
Aomoto complex of logarithmic Orlik-Solomon forms; they are subcomplexes of the de Rham complexes of standard local systems from [SV91]. (In fact the stratification itself depends on a local system).

This way we get double complexes with one differential induced by the de Rham differential and the other one being the residue. The residue differential gives rise to BGG-like complexes. For the trivial local system we get the complexes considered in [BG92]; in our case the combinatorics of the “Schubert stratification” depends on the Cartan matrix and a finite number of dominant weights.

We illustrate this construction for $\mathfrak{g} = \mathfrak{sl}_2$. In this case we obtain the BGG resolutions of tensor products of finite dimensional $\mathfrak{g}$-modules, and the complex associated with our double complex calculates the intersection cohomology of the corresponding local system.

We expect to develop a similar picture for Kac-Moody algebras with nontrivial Serre’s relations. In this program, one considers discriminantal arrangements associated with a Kac-Moody algebra $\mathfrak{g}$, see [SV91]. One resolves the singularities of such an arrangement and considers the associated double complex of Orlik-Solomon forms as in this paper. Serre’s relations of $\mathfrak{g}$ correspond to certain strata of the resolution. By using these strata, one expects to define a double subcomplex of the double complex. The spaces of the double subcomplex will correspond to the subspaces of the associated BGG resolution.

In Section 2, we consider a complex analytic manifold $X$, a divisor $D \subset X$ with normal crossings and a holomorphic flat connection on $X$. We construct a complex which calculates the cohomology of $X$ with coefficients in the local system associated with the flat connection.

In Section 3, we define an Orlik-Solomon manifold, a flat connection with logarithmic singularities on an Orlik-Solomon manifold, and the associated finite-dimensional Aomoto complex. Theorem 3.2 says that the Aomoto complex calculates the cohomology of the Orlik-Solomon manifold with coefficients in the local system associated with the connection. Theorem 3.2 is our first main result.

In Section 4, we discuss the minimal resolution of singularities of an arrangement. In Section 5, we introduce weighted Orlik-Solomon manifolds associated with weighted arrangement of hyperplanes. In Section 6, we review the definition of the BGG resolution for the Lie algebra $\mathfrak{sl}_2$. In Section 7, we realize geometrically the $\mathfrak{sl}_2$ BGG resolution as the skew-symmetric part of the Aomoto complex of a suitable weighted Orlik-Solomon manifold. Theorem 7.7 is our second main result. In Section 7.8, we discuss the relations between the BGG resolution and the complex of flag forms. In Section 7.9, we discuss the relations between the BGG resolution and intersection cohomology.

Acknowledgements. — We thank A. Beilinson, V. Ginzburg, H. Terao for useful discussions and the Max Planck Institute for Mathematics for hospitality.
2. Residue complex of a filtered manifold

2.1. Local system of a flat connection. — Let $X$ be a smooth connected complex analytic manifold. Given a natural number $r$, let $\nabla$ be a holomorphic flat connection on the trivial bundle $X \times \mathbb{C}^r \to X$. The sheaf $\mathcal{L}$ on $X$ of flat sections of $\nabla$ is a locally constant sheaf. If $s$ is a differential form with values in $\mathbb{C}^r$, we denote $d_{\mathcal{L}}s := \nabla s = ds + \omega \wedge s$ where $\omega$ is the connection form, a differential 1-form with values in $\text{End}(\mathcal{C}^r)$. We have $d_{\mathcal{L}}^2 = 0$.

Let $(\Omega^* \mathcal{L} \otimes \mathcal{C}^r, d_{\mathcal{L}})$ be the de Rham complex of sheaves of $\mathbb{C}^r$-valued holomorphic differential forms on $X$ with differential $d_{\mathcal{L}}$. The cohomology $H^*(X; \mathcal{L})$ of $X$ with coefficients in $\mathcal{L}$ is canonically isomorphic to the hypercohomology $H^*(X, \Omega^* \mathcal{L} \otimes \mathcal{C}^r)$.

2.2. Residue complex of sheaves. — Let $D \subset X$ be a divisor with normal crossings. Namely, we assume that $X$ is covered by charts such that in each chart $D$ is the union of several coordinate hyperplanes or the empty set. Such charts are called linearizing. We define $\mathcal{L} = \{X = Z_0 \supset D = Z_1 \supset Z_2 \supset \cdots \}$ the associated filtration of $X$ by closed subsets as follows. A point $x \in X$ belongs to $Z_i$ if in a linearizing chart $x$ belongs to the intersection of $i$ distinct coordinate hyperplanes of $D$. Thus $\text{codim}_X Z_i = i$ if $Z_i$ is nonempty. We denote by $C_{i,j}, j = 1, 2, \ldots$, the connected components of $Z_i \setminus Z_{i+1}$. Each $C_{i,j}$ is a smooth connected complex analytic submanifold of $X$ of codimension $i$. We set $C_{0,1} = X \setminus D$.

Let $\Omega^j_{C_{i,j}}$ be the sheaf of holomorphic differential $j$-forms on $C_{i,j}$. Let $f : C_{i,j} \hookrightarrow X$ be the natural embedding and $f_* \Omega^j_{C_{i,j}}$ the direct image sheaf. We denote $\Omega^j_{X,\mathcal{L}} = \bigoplus_{i,j} f_* \Omega^j_{C_{i,j}}$.

Let $d_{\mathcal{L}} : f_* \Omega^j_{C_{i,j}} \otimes \mathbb{C}^r \to f_* \Omega^{j+1}_{C_{i,j}} \otimes \mathbb{C}^r$ be the differential of the connection $\nabla|_{C_{i,j}}$ and $\text{res} : f_* \Omega^j_{C_{i,j}} \otimes \mathbb{C}^r \longrightarrow f_* \Omega^{j-1}_{C_{i+1,j'}} \otimes \mathbb{C}^r$ the residue map, if $C_{i+1,j'}$ lies in the closure $\overline{C_{i,j}}$, and the zero map otherwise. The map $\overline{d} = d_{\mathcal{L}} + \text{res}$ defines the complex of sheaves on $X$,

$$0 \longrightarrow \Omega^0_{X,\mathcal{L}} \otimes \mathcal{C}^r \overset{\overline{d}}{\longrightarrow} \Omega^1_{X,\mathcal{L}} \otimes \mathcal{C}^r \overset{\overline{d}}{\longrightarrow} \Omega^2_{X,\mathcal{L}} \otimes \mathcal{C}^r \overset{\overline{d}}{\longrightarrow} \cdots$$

The natural embeddings $\Omega^j_{X} \otimes \mathbb{C}^r \hookrightarrow \Omega^j_{C_{n+1}} \otimes \mathbb{C}^r \hookrightarrow \Omega^j_{X,\mathcal{L}} \otimes \mathbb{C}^r$ define an injective homomorphism of complexes

$$\Omega^*_{X} \otimes \mathbb{C}^r, d_{\mathcal{L}} \hookrightarrow (\Omega^*_{X,\mathcal{L}} \otimes \mathbb{C}^r, \overline{d}).$$

Theorem 2.1. — The homomorphism (2.1) is a quasi-isomorphism.

Proof. — It is enough to check this statement locally on $X$. In that case we may assume that $X = \{z = (z_1, \ldots, z_k) \in \mathbb{C}^k \mid |z| < 1\}$ and $D$ is the union of several coordinate hyperplanes in $X$. For that example, the statement is checked by direct calculation. \qed
2.3. Residue complex of global sections. — Let $\Gamma(C_{i,j}, \Omega^r_{C_{i,j}})$ be the space of global sections of $\Omega^r_{C_{i,j}}$. Denote

$$
\Gamma(X, \mathcal{F}; \mathbb{C}^r) = \bigoplus_{i,j} \Gamma(C_{i,j}, \Omega^{r-2i}_{C_{i,j}}) \otimes \mathbb{C}^r.
$$

The map $\tilde{d} = d_{\mathcal{F}} + \text{res}$ defines the complex of vector spaces

$$
0 \rightarrow \Gamma^0(X, \mathcal{F}; \mathbb{C}^r) \xrightarrow{\tilde{d}} \Gamma^1(X, \mathcal{F}; \mathbb{C}^r) \xrightarrow{\tilde{d}} \Gamma^2(X, \mathcal{F}; \mathbb{C}^r) \xrightarrow{\tilde{d}} \cdots
$$

Theorem 2.2. — In addition to assumptions of Sections 2.1 and 2.2, we assume that for any $i, j$, the manifold $C_{i,j}$ is a Stein manifold. Then there is the natural isomorphism $H^*(X; \mathbb{L}) \cong H^*((\Gamma(C_{i,j}, \Omega^r_{C_{i,j}}) \otimes \mathbb{C}^r, d_{\mathcal{F}}))$.

Proof. — For the Stein manifold $C_{i,j}$ the complex $((\Gamma(C_{i,j}, \Omega^r_{C_{i,j}}) \otimes \mathbb{C}^r, d_{\mathcal{F}}))$ calculates $H^*(C_{i,j}; \mathbb{L})$. This fact and Theorem 2.1 imply Theorem 2.2. \qed

3. Logarithmic residue complex of Orlik-Solomon forms

3.1. Affine arrangements. — Let $A = \{H_i\}_{i \in I}$ be an affine arrangement of hyperplanes, i.e., $\{H_i\}_{i \in I}$ is a finite nonempty collection of distinct hyperplanes in the affine complex space $\mathbb{C}^k$. Denote $U = \mathbb{C}^k \setminus \bigcup_{i \in I} H_i$. We denote by $\Omega^r_U$ the sheaf of holomorphic $r$-forms on $U$.

For any $i \in I$, choose a degree one polynomial function $f_i$ on $\mathbb{C}^k$ whose zero locus equals $H_i$. Define $\omega_i = d \log f_i = df_i/f_i \in \Gamma(U, \Omega^1_U)$. Given a natural number $r$, we choose matrices $P_i \in \text{End}(\mathbb{C}^r)$, $i \in I$. Denote

$$
\omega = \sum_{i \in I} \omega_i \otimes P_i \in \Gamma(U, \Omega^1_U) \otimes \text{End}(\mathbb{C}^r).
$$

The form $\omega$ defines the connection $d + \omega$ on the trivial bundle $U \times \mathbb{C}^r \rightarrow U$. We suppose that $d + \omega$ is flat. Let $\mathcal{L}$ be the sheaf on $U$ of flat sections. Then $(\Omega^r_U \otimes \mathbb{C}^r, d_{\mathcal{L}})$ is the complex of sheaves of $\mathbb{C}^r$-valued holomorphic differential forms on $U$ with differential $d_{\mathcal{L}} = d + \omega$.

Define finite dimensional Orlik-Solomon subspaces $A^p(A) \subset \Gamma(U, \Omega^p_U)$ as the $\mathbb{C}$-linear subspaces generated by all forms $\omega_i \wedge \cdots \wedge \omega_i$. Then the exterior multiplication by $\omega$ defines the complex

$$
0 \rightarrow A^0 \otimes \mathbb{C}^r \xrightarrow{\omega} A^1 \otimes \mathbb{C}^r \xrightarrow{\omega} A^2 \otimes \mathbb{C}^r \xrightarrow{\omega} \cdots
$$

as a subcomplex of $(\Gamma(U, \Omega^r_U \otimes \mathbb{C}^r), d_{\mathcal{L}})$. We call $(A^\bullet \otimes \mathbb{C}^r, \omega)$ the Aomoto complex of $(U, d + \omega)$.

Let $Y$ be any smooth compactification of $\mathbb{C}^k$ such that $H_\infty$ is a divisor. Write $H = H_\infty \cup (\bigcup_{i \in I} H_i)$. Then $U = Y \setminus H$. (Typical examples for $Y$ include the complex projective space $\mathbb{P}^k$, $(\mathbb{P}^1)^k$ and any toric compactification of $\mathbb{C}^k$.) Note that $\omega$ can be uniquely extended to be an $\text{End}(\mathbb{C}^r)$-valued rational 1-form $\omega$ on $Y$.

Theorem 3.1 ([ESV92, STV95]). — Suppose $\pi : X \rightarrow Y$ is a blow-up of $Y$ with centers in $H$ such that 1) $X$ is nonsingular, 2) $\pi^{-1}H$ is a normal crossing divisor,
3) none of the eigenvalues of the residue of $\pi^*\omega$ along any component of $\pi^{-1}H$ is a positive integer. Then the inclusion $$(A^* \otimes \mathbb{C}', \omega) \hookrightarrow (\Gamma(U, \Omega^r_H) \otimes \mathbb{C}', d_Z)$$ is a quasi-isomorphism.

**Remark.** — Assume that the pair $(X, \omega)$ satisfies conditions 1) and 2) of Theorem 3.1 but not condition 3). Then for almost all $\kappa \in \mathbb{C}^*$, the pair $(X, \omega/\kappa)$ satisfies all of the conditions 1)-3) of Theorem 3.1.

### 3.2. Orlik-Solomon manifolds.

Let $X$ be a smooth connected complex analytic manifold, $\dim X = k$. Let $D \subset X$ be a divisor with normal crossings and $\mathcal{Z} = \{X = Z_0 \supset D = Z_1 \supset Z_2 \supset \cdots\}$ the associated filtration of $X$ by closed subsets. We denote by $C_{i,j}$, $j = 1, 2, \ldots$, the connected components of $Z_i \setminus Z_{i+1}$ and set $C_{0,1} = X \setminus D$.

Assume that for any $C_{i,j}$ we have:

1. An affine arrangement $\mathcal{A}_{i,j} = \{H_m\}_{m \in \mathbb{Z}_{i,j}}$ in $\mathbb{C}^{k-1}$ with complement $U_{i,j} = \mathbb{C}^{k-1} \setminus \bigcup_{m \in \mathbb{Z}_{i,j}} H_m$ and an analytic isomorphism $\varphi_{i,j} : U_{i,j} \to C_{i,j}$.

Assume that these objects have the following property.

2. For any $i, j$, denote by $A^*(U_{i,j})$ the Orlik-Solomon spaces of $U_{i,j}$. Let $C_{i+1,j}$ lie in the closure $\overline{U_{i,j}}$ and

$$\text{res} : \Gamma(C_{i,j}, \Omega^r_{C_{i,j}}) \longrightarrow \Gamma(C_{i+1,j}, \Omega^{r-1}_{C_{i+1,j}}).$$

the residue map. Then the image of $A^*(U_{i,j})$ under the composition $(\varphi_{i+1,j'})^* \circ \text{res} \circ \left((\varphi_{i,j})^{-1}\right)^*$ lies in $A^*(U_{i+1,j'})$.

We say that $(X, D)$ is an Orlik-Solomon manifold if it has charts (i) with property (ii).

The images of Orlik-Solomon spaces $A^*(U_{i,j})$ under the isomorphism $\varphi_{i,j}$ give finite-dimensional subspaces of $\Gamma(C_{i,j}, \Omega^r_{C_{i,j}})$. We call these subspaces the Orlik-Solomon spaces of $C_{i,j}$ and denote by $A^*(C_{i,j})$.

**Remark.** — Denote by $K = \{(0, 1), \ldots\}$ the set of all pairs $(i, j)$ appearing as indices of components $C_{i,j}$ in the decomposition of the pair $(X, D)$. Let $K_0 \subset K$ be any subset which does not contain $(0, 1)$. Denote $C_{K_0} \subset X$ the closure of $\bigcup_{(i,j) \in K_0} C_{i,j}$. Denote $X_{K_0} = X \setminus C_{K_0}$, $D_{K_0} = D \setminus C_{K_0}$. Then $X_{K_0}$ is a smooth connected complex analytic manifold and $D_{K_0} \subset X_{K_0}$ is a divisor with normal crossings. If $(X, D)$ is an Orlik-Solomon manifold, then $(X_{K_0}, D_{K_0})$ has the induced structure of an Orlik-Solomon manifold.

We describe examples of Orlik-Solomon manifolds in Section 4.2.

### 3.3. Aomoto complexes.

Assume that $(X, D)$ is an Orlik-Solomon manifold and $\nabla = d_Z + d + \omega$ is a holomorphic flat connection on $X \times \mathbb{C}' \to X$. We say that $\nabla$ is a flat connection with logarithmic singularities on the Orlik-Solomon manifold if the following property holds.

---

J.E.P. — M., 2014, tome 1
(iii) For any $i,j$, the induced flat connection $\nabla_{i,j} := (\phi_{i,j})^* \nabla$ on $U_{i,j}$ has the form described in Section 3.1. Namely, $\nabla_{i,j} = d + \omega_{i,j}$, where

$$\omega_{i,j} = \sum_{m \in I_{i,j}} \omega_m \otimes P_m$$

for suitable matrices $P_m \in \text{End}(C^r)$.

If $\nabla$ is a flat connection with logarithmic singularities on the Orlik-Solomon manifold $(X,D)$, then the exterior multiplication by $\omega$ defines a finite-dimensional complex $A^\ell((C^r) \otimes C^r, \omega)$ as a subcomplex of $(\Gamma(C^r) \otimes C^r, d_L = d + \omega)$.

We denote

$$A^\ell(X, \mathcal{Z}; C^r) = \bigoplus_{i,j} A^\ell - 2i(C_{i,j}) \otimes C^r.$$

The map $\omega + \text{res}$ realizes the complex

$$0 \rightarrow A^0(X, \mathcal{Z}; C^r) \xrightarrow{\omega + \text{res}} A^1(X, \mathcal{Z}; C^r) \xrightarrow{\omega + \text{res}} A^2(X, \mathcal{Z}; C^r) \xrightarrow{\omega + \text{res}} \cdots$$

as a subcomplex of $(\Gamma(X, \mathcal{Z}; C^r), \tilde{d})$.

**Theorem 3.2.** — Assume that $\nabla = d + \omega$ is a flat connection with logarithmic singularities on the Orlik-Solomon manifold $(X,D)$. Assume that for any $i,j$, the form $\omega_{i,j}$ on $U_{i,j}$ satisfies the conditions of Theorem 3.1 for a suitable resolution of singularities mentioned in Theorem 3.1. Then the embedding $(A^\ell(X, \mathcal{Z}; C^r), \omega + \text{res}) \hookrightarrow (\Gamma(X, \mathcal{Z}; C^r), d)$ is a quasi-isomorphism.

**Proof.** — By Theorem 3.1, the embedding

$$(A^\ell(C_{i,j}) \otimes C^r, \omega) \hookrightarrow (\Gamma(C_{i,j}, \Omega^*_{C_{i,j}}) \otimes C^r, d_L)$$

is a quasi-isomorphism. This implies Theorem 3.2. □

**Corollary 3.3.** — Assume that $\nabla = d + \omega$ is a flat connection with logarithmic singularities on the Orlik-Solomon manifold $(X,D)$. For $\kappa \in C^r$, consider the flat connection $\nabla_\kappa = d + \omega/\kappa$ and the associated embedding $(A^\ell(X, \mathcal{Z}; C^r), \omega/\kappa + \text{res}) \hookrightarrow (\Gamma(X, \mathcal{Z}; C^r), d + \omega/\kappa + \text{res})$. Then for generic $\kappa$ this embedding is a quasi-isomorphism.

4. Resolution of singularities of arrangements

4.1. Minimal resolution of a hyperplane-like divisor. — Let $Y$ be a smooth connected complex analytic manifold and $H$ a divisor. The divisor $H$ is hyperplane-like if $Y$ can be covered by coordinate charts such that in each chart $H$ is the union of hyperplanes. Such charts are called linearizing.

Let $H$ be a hyperplane-like divisor, $V$ a linearizing chart. A local edge of $H$ in $V$ is any nonempty irreducible intersection in $V$ of hyperplanes of $H$ in $V$. A local edge is dense if the subarrangement of all hyperplanes in $V$ containing the edge is irreducible: the hyperplanes cannot be partitioned into nonempty sets so that, after a change of coordinates, hyperplanes in different sets are in different coordinates. In particular, each hyperplane is a dense edge. An edge of $H$ is the maximal analytic continuation in $Y$.
edges of dense vertices of \( H \)

Let \( H \subset Y \) be a hyperplane-like divisor. Let \( \pi: \tilde{Y} \to Y \) be the minimal resolution of singularities of \( H \) in \( Y \). The minimal resolution is constructed by first blowing-up dense vertices of \( H \), then by blowing-up the proper preimages of dense one-dimensional edges of \( H \) and so on, see [DCP95, Var95, STV95].

We have two basic examples of pairs \((Y, H)\).

**4.1.1. Projective arrangement.**  Let \( \mathcal{A} = \{H_t\}_{t \in I} \) be a nonempty finite collection of distinct hyperplanes in the complex projective space \( \mathbb{P}^k \). Denote \( H = \bigcup_{t \in I} H_t \). Then \( H \subset \mathbb{P}^k \) is a hyperplane-like divisor. Denote \( U = \mathbb{P}^k \setminus H \).

For any \( \ell, m \in I \), we have \( H_\ell \setminus H_m = \text{div}(f_\ell,m) \) for some rational function \( f_\ell,m \) on \( \mathbb{P}^k \). Define \( \omega_{\ell,m} = d \log f_\ell,m \). For \( 1 \leq p \leq k \), we define the Orlik-Solomon space \( A^p(U) \) as the \( \mathbb{C} \)-linear span of \( \omega_{\ell_1,m_1} \wedge \cdots \wedge \omega_{\ell_p,m_p} \).

Given a natural number \( r \), we choose matrices \( P_t \in \text{End}(\mathbb{C}^r) \), \( t \in I \), such that \( \sum_t P_t = 0 \). Fix \( m \in I \) and define

\[ \omega = \sum_{t \in I} \omega_{t,m} \otimes P_t. \]

The form \( \omega \) defines the connection \( d + \omega \) on \( U \times \mathbb{C}^r \to U \). We call \( d + \omega \) a connection with logarithmic singularities on the complement of the projective arrangement.

**4.1.2. Discriminantal arrangement.**  Let \( Y = (\mathbb{P}^1)^k \). For \( \ell = 1, \ldots, k \), we fix an affine coordinate \( t_\ell \) on the \( \ell \)-th factor of \( Y \). For \( 1 \leq \ell < m \leq k \), the subset \( H_{\ell,m} \subset Y \) defined by the equation \( t_\ell - t_m = 0 \) is called a diagonal hyperplane. For \( \ell, 1 \leq \ell \leq k \) and \( z \in \mathbb{C} \cup \{\infty\} \), the subset \( H_{\ell}(z) \subset Y \) defined by the equation \( t_\ell - z = 0 \) is called a coordinate hyperplane. If \( z \in \mathbb{C} \) (resp. \( z = \infty \)), we call the coordinate hyperplane finite (resp. infinite).

A discriminantal arrangement in \( Y \) is a finite collection of diagonal and coordinate hyperplanes, which includes all infinite coordinate hyperplanes \( H_\ell(\infty), \ell = 1, \ldots, k \), see [SV91]. Define by \( H \) the union of all of the hyperplanes of the arrangement. Then \( H \subset Y \) is a hyperplane-like divisor. Denote \( U = Y \setminus H \).

To every diagonal hyperplane \( H_{\ell,m} \), we assign the 1-form \( \omega_{H_{\ell,m}} = d \log(t_\ell - t_m) \). To every finite coordinate hyperplane \( H_\ell(z) \), we assign the 1-form \( \omega_{H_\ell(z)} = d \log t_\ell - z \). These are holomorphic forms on \( U \). We define the Orlik-Solomon spaces \( A^*(U) \) as the graded components of the exterior \( \mathbb{C} \)-algebra generated by the 1-forms associated with the diagonal and finite coordinate hyperplanes.

Fix a natural number \( r \). For any diagonal or finite coordinate hyperplane \( H \) of the arrangement we choose a matrix \( P_H \in \text{End}(\mathbb{C}^r) \). Define

\[ \omega = \sum \omega_H \otimes P_H, \]

where the sum is over all diagonal and finite coordinate hyperplanes of the discriminantal arrangement. This form \( \omega \) defines the connection \( d + \omega \) on the trivial bundle \( U \times \mathbb{C}^r \to U \). We call \( d + \omega \) a connection with logarithmic singularities on the complement of the discriminantal arrangement.
4.2. Examples of Orlik-Solomon manifolds

4.2.1. Minimal resolution of singularities of a projective arrangement

Let $\mathcal{A} = \{H_\ell\}_{\ell \in I}$ be a projective arrangement of hyperplanes in $\mathbb{P}^k$. Denote $Y = \mathbb{P}^k$ and $H = \bigcup_{\ell \in I} H_\ell$. Let $\pi : \tilde{Y} \to Y$ be the minimal resolution of singularities of $H$ in $Y$ and $\tilde{H} = \pi^{-1}H$. Then $\tilde{H} \subset \tilde{Y}$ is a divisor with normal crossings. For the pair $(\tilde{Y}, \tilde{H})$, we introduce components $C_{i,j} \subset \tilde{Y}$ as in Section 2. It is clear from the construction of the minimal resolution that each $C_{i,j}$ is naturally isomorphic to the complement of an affine arrangement and these isomorphisms have property (ii) of Section 3.2. Thus $(\tilde{Y}, \tilde{H})$ has the natural structure of an Orlik-Solomon manifold.

4.2.2. Minimal resolution of singularities of a discriminantal arrangement

Let $\mathcal{A} = \{H_\ell\}_{\ell \in I}$ be a discriminantal arrangement of hyperplanes in $(\mathbb{P}^1)^k$. Denote $Y = (\mathbb{P}^1)^k$ and $H = \bigcup_{\ell \in I} H_\ell$. Let $\pi : \tilde{Y} \to Y$ be the minimal resolution of singularities of $H$ in $Y$ and $\tilde{H} = \pi^{-1}H$. Then $\tilde{H} \subset \tilde{Y}$ is a divisor with normal crossings. For the pair $(\tilde{Y}, \tilde{H})$, we introduce components $C_{i,j} \subset \tilde{Y}$ as in Section 2. It is clear from the construction of the minimal resolution that each $C_{i,j}$ is naturally isomorphic to the complement of an affine arrangement and these isomorphisms have property (ii) of Section 3.2. Thus $(\tilde{Y}, \tilde{H})$ has the natural structure of an Orlik-Solomon manifold.

5. Weighted arrangements

5.1. Weighted projective arrangement. Let $\mathcal{A} = \{H_\ell\}_{\ell \in I}$ be a projective arrangement of hyperplanes in $Y = \mathbb{P}^k$. Denote $H = \bigcup_{\ell \in I} H_\ell$, $U = Y \setminus H$.

The arrangement $\mathcal{A}$ is weighted if a map $a : I \to \mathbb{C}, \ell \mapsto a_\ell$, is given such that $\sum_{\ell \in I} a_\ell = 0$. The number $a_\ell$ is called the weight of $H_\ell$. Let $X_\alpha$ be an edge of $\mathcal{A}$. Denote $I_\alpha = \{\ell \in I \mid H_\ell \supset X_\alpha\}$. The number $a_\alpha = \sum_{\ell \in I_\alpha} a_\ell$ is called the weight of $X_\alpha$. The edge $X_\alpha$ is resonant if $a_\alpha = 0$.

Fix $m \in I$ and define

$$\omega_a = \sum_{\ell \in I} \omega_{\ell,m} \otimes a_\ell,$$

see Section 4.1.1. The form $\omega_a$ defines the flat connection $d + \omega_a$ on $U \times \mathbb{C} \to U$. We call $d + \omega_a$ the connection associated with weights $a$.

Let $\pi : \tilde{Y} \to Y$ be the minimal resolution of singularities of $H$. Denote $\tilde{H} = \pi^{-1}H$. The irreducible components of $\tilde{H}$ are labeled by dense edges $X_\alpha$ of $H$. Such a component will be denoted by $\tilde{H}_\alpha$. Consider $(\tilde{Y}, \tilde{H})$ with its natural structure of an Orlik-Solomon manifold, see Section 4.2.1.

Denote $\tilde{\omega}_a = \pi^*\omega_a$. The form $\tilde{\omega}_a$ is regular on an irreducible component of $\tilde{H}$ if and only if the corresponding dense edge of $H$ is resonant.

Let $J$ be the set of all nonresonant dense edges of $H$ and $\bar{J}$ any set of dense edges such that $J \subseteq \bar{J}$. Denote $\tilde{H}_{\bar{J}} = \bigcup_{X_\alpha \in \bar{J}} \tilde{H}_\alpha$, $X = \tilde{Y} \setminus \tilde{H}_{\bar{J}}$, $D = \tilde{H} \setminus \tilde{H}_{\bar{J}}$.

Then $(X, D)$ is the Orlik-Solomon manifold with respect to the structure induced from $(\tilde{Y}, \tilde{H})$, see Section 3.2. The form $\tilde{\omega}_a$ is regular on $X$ and $d + \tilde{\omega}_a$ is a flat connection with logarithmic singularities on the Orlik-Solomon manifold $(X, D)$. Thus we may
construct the associated complex \((A^\star(X, \mathcal{Z}), \tilde{\omega}_a + \text{res})\) and apply Theorem 3.2 and Corollary 3.3 to the triple \((X, D, d + \tilde{\omega}_a)\). The complex \((A^\star(X, \mathcal{Z}), \tilde{\omega}_a + \text{res})\) will be called the Aomoto complex of the weighted Orlik-Solomon manifold \((X, D)\).

5.2. Weighted discriminantal arrangement. — Let \(\mathcal{A} = \{H_\ell\}_{\ell \in I}\) be a discriminantal arrangement of hyperplanes in \(Y = (\mathbb{P}^1)^k\). Denote \(H = \bigcup_{\ell \in I} H_\ell, U = Y \setminus H\).

According to the definition in Section 4.1.2, the discriminantal arrangement contains the infinite coordinate hyperplanes \(H_p(\infty), p = 1, \ldots, k\). Let \(I_{\text{fin}} \subset I\) be the set of indices of the remaining hyperplanes of \(\mathcal{A}\).

The discriminantal arrangement \(\mathcal{A}\) is weighted if a map \(a : I_{\text{fin}} \to \mathbb{C}, \ell \mapsto a_\ell\), is given. The number \(a_\ell\) is the weight of \(H_\ell, \ell \in I_{\text{fin}}\). We also write \(a(H_\ell) := a_\ell\).

We extend this map to the map \(a : I \to \mathbb{C}\) as follows. We set the weight of an infinite coordinate hyperplane \(H_p(\infty)\) to be the number \(-\sum q \in I_{\text{fin}}\) where the sum is over all \(q \in I_{\text{fin}}\) such that \(H_q\) is of the form \(t_p - t_i = 0\) for some \(i\) or of the form \(t_p - z = 0\) for some \(z \in \mathbb{C}\).

Let \(X_\alpha\) be an edge of \(\mathcal{A}\). Denote \(I_\alpha = \{\ell \in I \mid H_\ell \supset X_\alpha\}\). The number \(a_\alpha = \sum_{\ell \in I_\alpha} a_\ell\) is the weight of \(X_\alpha\). The edge \(X_\alpha\) is resonant if \(a(X_\alpha) = 0\).

We define

\[
\omega_a = \sum_{\ell \in I_{\text{fin}}} \omega_{H_\ell} \otimes a_\ell,
\]

see Section 4.1.2. The form \(\omega_a\) defines the flat connection \(d + \omega_a\) on \(U \times \mathbb{C} \to U\). We call \(d + \omega_a\) the connection associated with weights \(a\).

Let \(\pi : \tilde{Y} \to Y\) be the minimal resolution of singularities of \(H\). Denote \(\tilde{H} = \pi^{-1}(H)\). The irreducible components of \(\tilde{H}\) are labeled by dense edges \(X_\alpha\) of \(H\). Such a component component will be denoted by \(\tilde{H}_\alpha\). Consider \((\tilde{Y}, \tilde{H})\) as the Orlik-Solomon manifold, see Section 4.2.2.

Denote \(\tilde{\omega}_a = \pi^\star \omega_a\). The form \(\tilde{\omega}_a\) is regular on an irreducible component of \(\tilde{H}\) if and only if the corresponding dense edge of \(H\) is resonant.

Let \(J\) be the set of all nonresonant dense edges of \(H\) and \(\tilde{J}\) any subset of dense edges such that \(J \subseteq \tilde{J}\). Denote \(H_{\tilde{J}} = \bigcup_{X_\alpha \in \tilde{J}} \tilde{H}_\alpha, X = \tilde{Y} \setminus H_{\tilde{J}}, D = \tilde{H} \setminus H_{\tilde{J}}\). Then \((X, D)\) is the Orlik-Solomon manifold with respect to the structure induced from \((\tilde{Y}, \tilde{H})\), see Section 3.2. The form \(\tilde{\omega}_a\) is regular on \(X\) and \(d + \tilde{\omega}_a\) is a flat connection with logarithmic singularities on the Orlik-Solomon manifold \((X, D)\). Thus we may construct the associated complex \(A^\star(X, \mathcal{Z}, \tilde{\omega}_a + \text{res})\) and apply Theorem 3.2 and Corollary 3.3 to the triple \((X, D, d + \tilde{\omega}_a)\). The complex \(A^\star(X, \mathcal{Z}, \tilde{\omega}_a + \text{res})\) will be called the Aomoto complex of the weighted Orlik-Solomon manifold \((X, D)\).

6. Highest weight representations of \(\mathfrak{sl}_2\)

6.1. Modules. — Consider the complex Lie algebra \(\mathfrak{sl}_2\) with standard basis \(e, f, h\) such that \([e, f] = h, [h, e] = 2e, [h, f] = -2f\). We have \(\mathfrak{sl}_2 = n_- \oplus h \oplus n_+\), where \(n_- = \mathbb{C}f, h = \mathbb{C}h, n_+ = \mathbb{C}e\).

Let \(V\) be an \(\mathfrak{sl}_2\)-module. For \(\lambda \in \mathbb{C}\), let \(V[\lambda] = \{v \in V \mid hv = \lambda v\}\) be the subspace of weight \(\lambda\). Assume that \(V\) has weight decomposition \(V = \bigoplus_\lambda V[\lambda]\) with

\[J.É.P. - M., 2014, tome 1\]
finite-dimensional spaces $V[\lambda]$. Then the restricted dual of $V$ is $V^* := \bigoplus_\lambda V[\lambda]^*$. The restricted dual has the contragredient $\mathfrak{sl}_2$-module structure: for $\varphi \in V^*$, we have $(\varphi, v) = (\varphi, f v) = (\varphi, ev)$, $(h \varphi, v) = (\varphi, hv)$. We have $V[\lambda]^* = V^*[\lambda]$ for any $\lambda$.

For the Lie algebra $\mathfrak{n}_-$ and a module $V$ we denote $C_*(\mathfrak{n}_-, V)$ the standard complex of $\mathfrak{n}_-$ with coefficients in $V$,

$$0 \longrightarrow C_0(\mathfrak{n}_-, V) \longrightarrow C_1(\mathfrak{n}_-, V) \longrightarrow 0,$$

where $C_0(\mathfrak{n}_-, V) = \mathfrak{n}_- \otimes V$, $C_1(\mathfrak{n}_-, V) = V$, and the map is $f \otimes v \mapsto f v$. We have the weight decomposition

$$C_*(\mathfrak{n}_-, V)[\lambda] = \bigoplus_{\lambda} C_*(\mathfrak{n}_-, V)[\lambda],$$

where $C_*(\mathfrak{n}_-, V)[\lambda]$ is

$$0 \longrightarrow \mathfrak{n}_- \otimes V[\lambda + 2] \longrightarrow V[\lambda] \longrightarrow 0.$$  

6.2. Verma modules. — For $m \in \mathbb{C}$, the Verma module $M_m$ is the infinite dimensional $\mathfrak{sl}_2$-module generated by a single vector $v_m$ such that $hv_m = mv_m$ and $ev_m = 0$. The vectors $f^j v_m$, $j = 0, 1, \ldots$, form a basis of $M_m$. The action is given by the formulas

$$f \cdot f^j v_m = f^{j+1} v_m, \quad h \cdot f^j v_m = (m - 2j) f^j v_m, \quad e \cdot f^j v_m = j(m - j + 1) f^{j-1} v_m.$$  

Consider the contragredient module $M_m^*$ with the basis $\varphi^j_m$, $j \in \mathbb{Z}_{\geq 0}$, dual to the basis $f^j v_m$ of $M_m$. We have

$$f \cdot \varphi^0_m = (j + 1)(m - j) \varphi^0_m, \quad h \cdot \varphi^j_m = (m - 2j) \varphi^j_m, \quad e \cdot \varphi^j_m = \varphi^{j-1}_m.$$  

The Shapovalov symmetric bilinear form on $M_m$ is defined by the conditions

$$S(v_m, v_m) = 1, \quad S(f x, y) = S(x, ey),$$

for all $x, y \in M_m$. The Shapovalov form defines the morphism of modules

$$S : M_m \longrightarrow M_m^*, \quad x \longmapsto S(x, \cdot).$$

The image $L_m := \text{Im}(S) \hookrightarrow M_m^*$ is irreducible.

If $m \notin \mathbb{Z}_{\geq 0}$, then $M_m$ is irreducible, otherwise the subspace with basis $f^j v_m$, $j \geq m + 1$, is a submodule which is identified with the Verma module $M_{m-2}$ under the map $M_{m-2} \hookrightarrow M_m$, $f^j v_{m-2} \mapsto f^{j+1} v_m$. The quotient $M_m/M_{m-2}$ is an irreducible module with basis induced by $v_m, f v_m, \ldots, f^m v_m$. The submodule $M_{m-2} \hookrightarrow M_m$ is the kernel of the Shapovalov form. The induced Shapovalov form on $M_m/M_{m-2}$ identifies $M_m$ with $M_{m-2}$ and $L_m \hookrightarrow M_m^*$.

We have the exact sequence of $\mathfrak{sl}_2$-modules

$$0 \longrightarrow L_m \longrightarrow M_m^* \longrightarrow M_{m-2}^* \longrightarrow 0,$$

which is called the BGG resolution of the irreducible $\mathfrak{sl}_2$-module $L_m$, see [BGG75]. We will keep two terms of this sequence

$$M_m^* \longrightarrow M_{m-2}^*$$
in which the epimorphism is denoted by $\iota$. We consider this map as a complex with terms in degree 0 and 1.

6.3. Tensor product of Verma modules. — For a vector $m = (m_1, \ldots, m_n) \in \mathbb{C}^n$, denote $|m| = m_1 + \cdots + m_n$. Consider the tensor product $\bigotimes_{a=1}^n M_{m_a}$ of Verma modules. For $J = (j_1, \ldots, j_n) \in \mathbb{Z}_{\geq 0}^n$, let

$$f^J v_m := f^{j_1} v_{m_1} \otimes \cdots \otimes f^{j_n} v_{m_n}.$$ 

The vectors $f^J v_m$ form a basis of $\bigotimes_{a=1}^n M_{m_a}$. We have

$$f \cdot f^J v_m = \sum_{a=1}^n f^{j_a+1} v_{m_a}, \quad h \cdot f^J v_m = (|m| - 2|J|) f^J v_m,$$

$$e \cdot f^J v_m = \sum_{a=1}^n j_a (m_a - j_a + 1) f^{j_a-1} v_{m_a},$$

where $J \pm 1_a = (j_1, \ldots, j_a \pm 1, \ldots, j_n)$.

We have the weight decomposition

$$\bigotimes_{a=1}^n M_{m_a} = \bigoplus_{k=0}^\infty \left( \bigotimes_{a=1}^n M_{m_a} \right) [|m| - 2k].$$

The basis in $\left( \bigotimes_{a=1}^n M_{m_a} \right) [|m| - 2k]$ is formed by the monomials $f^J v_m$ with $|J| = k$.

Consider the restricted dual space $\left( \bigotimes_{a=1}^n M_{m_a} \right)^\ast$ with the weight decomposition

$$\left( \bigotimes_{a=1}^n M_{m_a} \right)^\ast = \bigoplus_{k=0}^\infty \left( \bigotimes_{a=1}^n M_{m_a} \right)^\ast [|m| - 2k].$$

The basis of $\left( \bigotimes_{a=1}^n M_{m_a} \right)^\ast [|m| - 2k]$ is formed by vectors

$$\varphi^J_m := \varphi^{j_1}_{m_1} \otimes \cdots \otimes \varphi^{j_n}_{m_n}$$

with $|J| = k$.

The $\mathfrak{sl}_2$-action is given by the formulas

$$f \cdot \varphi^J_m = \sum_{a=1}^n (j_a + 1)(m_a - j_a) \varphi^{j_a+1}_{m_a}, \quad h \cdot \varphi^J_m = (|m| - 2|J|) \varphi^{j_a+1}_{m_a}, \quad e \cdot \varphi^J_m = \sum_{a=1}^n \varphi^{j_a-1}_{m_a}.$$ 

6.4. Tensor product of complexes. — Let coordinates of $m = (m_1, \ldots, m_n)$ be positive integers. For $a = 1, \ldots, n$, denote by $A_{m_a}^0 \xrightarrow{\iota_a} A_{m_a}^i$ the complex $M_{m_a}^\ast \xrightarrow{\iota_a} M_{m_a-2}^\ast$. Consider the tensor product $(A_{m_a}^i, \iota)$ of these complexes, where

$$A_{m_a}^i = \bigoplus_{i_1 + \cdots + i_n = i} A_{m_a}^{i_1} \otimes \cdots \otimes A_{m_a}^{i_n}, \quad i = 0, \ldots, n,$$

with differential

$$\iota : x_1 \otimes \cdots \otimes x_n \longmapsto \sum_{a=1}^n (-1)^{\deg x_1 + \cdots + \deg x_{a-1}} x_1 \otimes \cdots \otimes \iota_a x_a \otimes \cdots \otimes x_n.$$ 

The differential is a morphism of $\mathfrak{sl}_2$-modules. We have

$$\bigotimes_{a=1}^n L_a = \ker(\iota : A_{m}^0 \longrightarrow A_{m}^i).$$
At all other degrees the complex \((A^*_{\mathfrak{m}}, \iota)\) is acyclic. Thus \((A^*_{\mathfrak{m}}, \iota)\) gives the resolution of \(\bigotimes_{a=1}^{n} L_a\) which we will call the BGG resolution of \(\bigotimes_{a=1}^{n} L_a\).

Consider the complex \(C_*(n, \bigotimes_{a=1}^{n} L_a)\),

\[
(6.3) \quad n_- \otimes A_{\mathfrak{m}}^* \xrightarrow{f} A_{\mathfrak{m}}^*.
\]

The differential \(f\) of this complex commutes with the differential \(\iota\) acting on \(A_{\mathfrak{m}}^*\).

Consider the complex \((B_{\mathfrak{m}}^*, \delta)\), where

\[
B_{\mathfrak{m}}^i = (n_- \otimes A_{\mathfrak{m}}^i) \oplus A_{\mathfrak{m}}^{i-1}, \quad i = 0, \ldots, n + 1,
\]

and

\[
\delta : f \otimes x + y \mapsto fx - f \otimes \iota x + \iota y.
\]

The embeddings

\[
(6.4) \quad \bigotimes_{a=1}^{n} L_{m_a} \hookrightarrow \bigotimes_{a=1}^{n} (L_{m_a})^* = B_{\mathfrak{m}}^0,
\]

\[
\bigotimes_{a=1}^{n} L_{m_a} \hookrightarrow (\bigotimes_{a=1}^{n} M_{m_a})^* \hookrightarrow B_{\mathfrak{m}}^1
\]

define the morphism of complexes

\[
(6.5) \quad C_*(n, \bigotimes_{a=1}^{n} L_{m_a}) \rightarrow (B_{\mathfrak{m}}^*, \delta).
\]

**Lemma 6.1. —** This morphism is a quasi-isomorphism.

This quasi-isomorphism will be called the BGG resolution of \(C_*(n, \bigotimes_{a=1}^{n} L_{m_a})\).

The complex \((B_{\mathfrak{m}}^*, \delta)\) has weight decomposition. For any \(\lambda \in \mathbb{C}\) we have

\[
B_{\mathfrak{m}}^i[\lambda] = (n_- \otimes A_{\mathfrak{m}}^i[\lambda + 2]) \oplus A_{\mathfrak{m}}^{i-1}[\lambda].
\]

In the next section we identify the complex \((B_{\mathfrak{m}}^*[|m| - 2k], \delta)\) with the skew-symmetric part of the Aomoto complex of a suitable weighted Orlik-Solomon manifold.

### 7. Discriminantal arrangements with \(\mathfrak{s}_2\) weights

#### 7.1. Weighted discriminantal arrangement in \(\mathbb{C}^k\)

Fix \(m = (m_1, \ldots, m_n)\) with positive integer coordinates and a positive integer \(k\). We assume that \(m_j \leq k - 1\) for \(j = 1, \ldots, n_0\) and \(m_j > k - 1\) for \(j = n_0 + 1, \ldots, n\). Fix \((z_1, \ldots, z_n) \in \mathbb{C}^n\) with distinct coordinates. Fix a generic nonzero number \(\kappa\).

Consider \(\mathbb{C}^k\) with coordinates \(t_1, \ldots, t_k\) and the weighted discriminantal arrangement \(\mathcal{A}\) consisting of the following hyperplanes: \(H_{t_j}\) defined by the equation \(t_i - t_j = 0\) for \(1 \leq i < j \leq k\), \(H_i^j\) defined by the equation \(t_i - z_j = 0\) for \(i = 1, \ldots, k, j = 1, \ldots, n\). The weights are \(a_{i,j} = 2/\kappa, a_i^j = -m_j/\kappa\). We denote by \(H \subset \mathbb{C}^k\) the union of all hyperplanes of \(\mathcal{A}\). Set \(U = \mathbb{C}^k \setminus H\).

The symmetric group \(S_k\) acts on \(\mathbb{C}^k\) by permutation of coordinates. The action preserves the weighted arrangement \(\mathcal{A}\).

For \(j = 1, \ldots, n_0\), let \(I \subset \{1, \ldots, k\}\) be a subset with \(m_j + 1\) elements. The edge \(X_I^j\) of \(\mathcal{A}\) defined by equations \(t_i = z_j\) for \(i \in I\), is resonant.
Lemma 7.1. — The edges $X^j_j$, $j = 1, \ldots, n_0$, $|I| = m_j + 1$, are the only resonant dense edges of $\mathcal{A}$.

Proof. — The dense edges of $\mathcal{A}$ have the form $t_{i_1} = \cdots = t_{i_\ell}$ or $t_{i_1} = \cdots = t_{i_\ell} = z_j$ for $2 \leq \ell \leq k$. One checks that the edges of the former type are not resonant, and edges of the latter type are resonant if and only if $\ell = m_j + 1 \leq k$. \hfill \Box

7.2. Skew-symmetric part of Aomoto complex of $U$. — The symmetric group $S_k$ naturally acts on the Orlik-Solomon spaces $A^*(U)$. The skew-symmetrization of a form $\eta \in A^*(U)$ is the form $\text{Skew} \eta := \sum_{\sigma \in S_k} (-1)^{\sigma} \eta$. The form $\text{Skew} \eta$ is skew-symmetric. More generally, if $G \subset S_k$ is a subgroup, then the $G$-skew-symmetrization of a form $\eta \in A^*(U)$ is the form $\text{Skew}_G \eta := \sum_{\sigma \in G} (-1)^{\sigma} \eta$.

The skew-symmetric part $A_{-}^*(U)$ of the Orlik-Solomon spaces $A^*(U)$ is described in [SV91]. We have $A_{-}^k(U) \neq 0$ only if $p = k - 1, k$. Let $J = (j_1, \ldots, j_n)$ be a vector with nonnegative integer coordinates and $|J| = k$. Define $\ell_0(J) = 0$ and $\ell_i(J) = j_1 + \cdots + j_i$ for $i = 1, \ldots, n$, and

$$\eta_{j,i} = d \log(t_{\ell_{i-1}(J)+1} - z_i) \wedge \cdots \wedge d \log(t_{\ell_i(J)} - z_1)$$

for $i = 1, \ldots, n$. Let $\omega_J$ be the skew-symmetrization of the $k$-form $\alpha_J \eta_{j,1} \wedge \cdots \wedge \eta_{j,n}$, where $\alpha_J = (\ell_J! j_1! \cdots j_n)!^{-1}$.

Let $J = (j_1, \ldots, j_n)$ be a vector with nonnegative integer coordinates and $|J| = k - 1$. Define the $(k - 1)$-form $\eta_J = \alpha_J \eta_{j,1} \wedge \cdots \wedge \eta_{j,n}$ as above, and then $\omega_J$ as the skew-symmetrization of $(-1)^k \eta_J$.

Lemma 7.2 ([SV91]). — The forms $\{\omega_J\}_{|J|=k}$ form a basis of $A_{-}^k(U)$. The forms $\{\omega_J\}_{|J|=k-1}$ form a basis of $A_{-}^{k-1}(U)$.

Define the form

$$\omega_n = \sum_{H \in \mathcal{A}} a_H \, d \log f_H \in A^k(U).$$

The form $\omega_n$ is symmetric with respect to the $S_k$-action.

Lemma 7.3 ([SV91]). — For any $m \in \mathbb{C}^n$, the complex $\wedge \omega_n : A_{-}^{k-1}(U) \rightarrow A_{-}^k(U)$ is isomorphic to the weight component of weight $|m| - 2k$ of the complex

$$\mathfrak{n} \otimes (\bigotimes_{a=1}^n M_{m_a})^* \rightarrow \bigotimes_{a=1}^n M_{m_a}^*.$$

The isomorphism sends $\omega_J$ to $f \otimes \varphi_m^J$ if $|J| = k - 1$ and to $\varphi_m^J$ if $|J| = k$.

7.3. Skew-symmetric forms on $\mathbb{P}^m$. — For a positive integer $m$, consider a subset $I = \{1 \leq i_0 < \cdots < i_m \leq k\}$ and the space $\mathbb{C}^{m+1}$ with coordinates $t_i, i \in I$. Consider the central arrangement in $\mathbb{C}^{m+1}$ consisting of coordinate hyperplanes and all diagonal hyperplanes. This arrangement is preserved by the action of the symmetric group $S_{m+1}$ which permutes the coordinates.
Consider the projectivization in \( \mathbb{P}^m \) of the initial arrangement. The functions \( u_{i\ell} = t_{i\ell}/t_{i0}, \ell = 1, \ldots, m \) are coordinates on an affine chart on \( \mathbb{P}^m \). In these coordinates the projectivization of the initial arrangement consists of hyperplanes \( u_{i\ell} = 0, \ u_{i\ell} - 1 = 0, \ u_{i\ell} - u_{iq} = 0 \) and the hyperplane at infinity. Denote \( U \subset \mathbb{P}^m \) the complement to the arrangement. Let \( A^*_U \) denote the skew-symmetric part of the Orlik-Solomon space \( A^*(U) \) with respect to the \( S_{m+1} \)-action.

**Lemma 7.4.** \( A^p(U) = 0 \) if \( p \neq m \), and \( \dim A^m(U) = 1 \). The form
\[
\mu_I = d \log u_{i_1} \wedge \cdots \wedge d \log u_{i_m}
\]
generates \( A^m(U) \).

**Proof.** Let \( \tilde{U} \) denote the complement of the original central arrangement in \( \mathbb{C}^{m+1} \). The skew-symmetric part of \( A^*(\tilde{U}) \) is two-dimensional, \( \dim A^p(\tilde{U}) = 1 \) for \( p = k, k+1 \). The skew-symmetrizations of
\[
\eta_{I,m} = d \log t_{i_1} \wedge \cdots \wedge d \log t_{i_m} \quad \text{and} \quad \eta_I = d \log t_{i_0} \wedge \cdots \wedge d \log t_{i_m}
\]
form a basis in \( A^*_U(\tilde{U}) \).

Using the identity \( d \log u_{i\ell} = d \log t_{i\ell} - d \log t_{i0} \), one identifies \( A^*(U) \) with a subspace of the Orlik-Solomon space \( A^*(\tilde{U}) \) of the initial central arrangement in \( \mathbb{C}^{m+1} \). By [Dim92, §6.1], the contraction along the Euler vector field \( \varepsilon = \sum_{\ell=0}^m t_{i\ell} \partial / \partial t_{i\ell} \), defines an epimorphism \( \partial: A^*(\tilde{U}) \to A^*(U) \), which restricts to an epimorphism \( A^*_U(\tilde{U}) \to A^*_U(U) \) of skew-symmetric forms. The map \( \partial \) is the boundary map in the acyclic complex studied in [OT92, §3.1], and also coincides with the residue map along the exceptional divisor in the blow-up of \( \mathbb{C}^{m+1} \) at the origin.

Under this identification, the skew-symmetrization of the form \( \eta_{I,m} \) equals a nonzero multiple of the form \( \mu_I \) considered as an element of \( A^*(\tilde{U}) \). The form \( \eta_I \) is skew-symmetric and its contraction along \( \varepsilon \) equals \( \mu_I \). The contraction of \( \mu_I \) along \( \varepsilon \) is trivial since \( \partial^2 = 0 \). Then \( A^p(U) = 0 \) for \( p \neq m \) and \( A^m(U) \) is spanned by \( \mu_I \). \( \square \)

### 7.4. Weighted Orlik-Solomon manifold

Consider the minimal resolution \( \pi:\tilde{Y} \to \mathbb{C}^k \) of singularities of \( H \), see Section 7.1. Denote \( \tilde{H} = \pi^{-1}H \). The irreducible components of \( \tilde{H} \) are labeled by dense edges of \( H \). We denote by \( X \) the manifold obtained from \( \tilde{Y} \) by deleting the union of all irreducible components of \( H \) corresponding to nonresonant dense edges. We set \( D = \tilde{H} \cap X \). Then \( D \subset X \) is a divisor with normal crossings and \( (X, D) \) is a weighted Orlik-Solomon manifold, see Sections 5.1 and 5.2. The symmetric group \( S_k \) acts on the Orlik-Solomon manifold \( (X, D) \).

The action preserves the weights.

Let \( \mathcal{P} = \{ X = Z_0 \supset D = Z_1 \supset Z_2 \supset \cdots \} \) be the associated filtration by closed subsets, and \( U = Z_0 \setminus Z_1 = X \setminus D \).

The irreducible components of \( D \) are labeled by resonant dense edges of \( H \). For \( j \in \{1, \ldots, n_0\} \) and \( I \subset \{1, \ldots, n\} \), \( |I| = m_j + 1 \), we denote by \( \tilde{H}_I^j \) the component corresponding to the resonant dense edge \( X_I^j \). We denoted by \( C_I^j \) the connected component of \( Z_1 \setminus Z_2 \) whose closure is \( \tilde{H}_I^j \). Then \( C_I^j \) is isomorphic to the complement
of the product of weighted arrangements in $\mathbb{P}^{m_j} \times C^{k-m_j-1}$, with weights induced by $\mathcal{A}$. If $I = \{1 \leq i_0 < \cdots < i_{m_j} \leq k\}$, then $u_{i_\ell}, \ell = 1, \ldots, m_j$, are coordinates on an affine chart on $\mathbb{P}^{m_j}$, see Section 7.3. The arrangement in $\mathbb{P}^{m_j}$ has hyperplanes $u_{i_\ell} = 0, u_{i_\ell} - 1 = 0, u_{i_\ell} - u_{i_q} = 0$ and the hyperplane at infinity. The weights induced by $\mathcal{A}$ are $-m_j/k$ for $u_{i_\ell} = 0$ and $2/k$ for $u_{i_\ell} - 1 = 0$ and $u_{i_\ell} - u_{i_q} = 0$. Coordinates on $C^{k-m_j-1}$ are $t_i, i \in \{1, \ldots, n\} \setminus I$. The arrangement in $C^{k-m_j-1}$ is the discriminantal arrangement with hyperplanes $t_i - t_q = 0, i, q \in \{1, \ldots, k\} \setminus I$ and $t_i - z_i = 0, i \in \{1, \ldots, k\} \setminus I, \ell \in \{1, \ldots, n\}$. The weights of this arrangement in $C^{k-m_j-1}$ induced from $\mathcal{A}$ are given by the pair $(m^j, \kappa)$, where $m^j = (m_1, \ldots, -m_j - 2, \ldots, m_n)$, see Section 7.1.

The set $\{C^j\}_{j, I}$ is the set of connected components of $Z_1 \setminus Z_2$. The group $S_k$ acts on $\{C^j\}_{j, I}$. For fixed $j$, the subset $\{C^j\}_{j, I}$ forms a single orbit.

For $p \geq 2$, the connected components $\{C^j\}_{j, I}$ of $Z_p \setminus Z_{p+1}$ are labeled by pairs $(j, I)$, where $j$ is a $p$-element subset of $\{1, \ldots, n_0\}$ and $I = \{I_j\}_{j \in j}$ is a set of pairwise disjoint subsets of $\{1, \ldots, k\}$ such that $|I_j| = m_j + 1$. The connected component $C^j_I$ is isomorphic to the complement of the product of weighted arrangements in $(\times_{j \in j} \mathbb{P}^{m_j}) \times C^{e(j)}$, where $e(j) = k - p - \sum_{j \in j} m_j$. For $j \in j$, if $I_j = \{1 \leq i_0 < \cdots < i_{m_j} \leq k\}$, then $u_{i_\ell}, \ell = 1, \ldots, m_j$, are coordinates on an affine chart on $\mathbb{P}^{m_j}$, see Section 7.3. The arrangement in $\mathbb{P}^{m_j}$ has hyperplanes $u_{i_\ell} = 0, u_{i_\ell} - 1 = 0, u_{i_\ell} - u_{i_q} = 0$ and the hyperplane at infinity. The weights induced by $\mathcal{A}$ are $-m_j/k$ for $u_{i_\ell} = 0$ and $2/k$ for $u_{i_\ell} - 1 = 0$ and $u_{i_\ell} - u_{i_q} = 0$. The space $C^{e(j)}$ has coordinates $t_i, i \in \{1, \ldots, k\} \setminus \bigcup_{j \in j} I_j$. The weighted arrangement in $C^{e(j)}$ is the discriminantal arrangement with weights given by the pair $(m^j, \kappa)$, where $m^j_i = -m_i - 2$ if $i \in j$ and $m^j_i = m_i$ otherwise, see Section 7.1.

The group $S_k$ acts on the set $\{C^j\}_{j, I}$. For fixed $j$, the subset $\{C^j\}_{j, I}$ forms a single orbit.

Let $C^\tilde{j}_I$ be a connected component of $Z_p \setminus Z_{p+1}$ and $C^\tilde{j}_I$ a connected component of $Z_{p+1} \setminus Z_{p+2}$. Then $C^\tilde{j}_I$ lies in the closure of $C^j_I$ if and only if $j \subset \tilde{j}$ and $I_j = \tilde{I}_j$ for every $j \in \tilde{j}$.

### 7.3. Skew-symmetric forms on weighted Orlik-Solomon manifold

For $p > 0$, fix a set $j = \{1 \leq j_1 < \cdots < j_p \leq n_0\}$. Consider the $S_k$-orbit $\{C^j\}_I$ of connected components of $Z_p \setminus Z_{p+1}$. Recall that $I = \{I_j\}_{j \in j}$ is a set of pairwise disjoint subsets of $\{1, \ldots, k\}$ such that $|I_j| = m_j + 1$. Each component $C^j_I$ is invariant with respect to the action of the subgroup $S_I = S_{m_{j_1}+1} \times \cdots \times S_{m_{j_p}+1} \times S_{e(j)} \subset S_k$, where $S_{m_{j_1}}$ is the group of permutations of elements of the subset $I_{j_1}$, $e(j) = k - p - \sum_{j=1}^{p} m_j$, and $S_{e(j)}$ is the group of permutations of elements of the subset $\{1, \ldots, k\} \setminus \bigcup_{j \in j} I_j$.

Our goal is to describe $S_k$-skew-symmetric Orlik-Solomon forms on $\bigcup_{j} C^j_I$. Such a form is uniquely determined by its restriction to one of the components in $\{C^j\}_I$.
That restriction is $S_I$-skew-symmetric. According to Sections 7.2 and 7.3, the $S_k$-skew-symmetric Orlik-Solomon forms on $\bigcup_I C^j_I$ are available only in degrees $k - p$ and $k - p - 1$.

Denote

$$d_j = \sum_{i=1}^{p-1} i(m_j + 1), \quad s_j = p + \sum_{i=1}^{p} m_j.$$ 

Select in $\{C_j^I\}$ the component $C^j_I$, where $I^0 = \{i_1^0, \ldots, i_p^0\}$ and

$$I_{j_i}^0 = \left\{1 + \sum_{i=1}^{p-1} (m_j + 1), \ldots, m_j + 1 + \sum_{i=1}^{p-1} (m_j + 1)\right\}, \quad i = 1, \ldots, p.$$ 

Let $K = (k_1, \ldots, k_n) \in \mathbb{Z}^n_{\geq 0}$, where $|K|$ equals $e(j)$ or $e(j) - 1$. Denote $\ell_0(K) = 0$ and $\ell_i(K) = k_1 + \cdots + k_i$, $i = 1, \ldots, n$. Denote

$$\eta^j_{K,i} = d \log(t_{j_i} + \ell_{i-1} + 1 - z_i) \land \cdots \land d \log(t_{j_i} + \ell_{i-1} + 2 - z_i), \quad i = 1, \ldots, n,$$

$$\alpha^j_K = (-1)^{d_j}((m_{j_1} + 1)! \cdots (m_{j_p} + 1)! k_1! \cdots k_n!)^{-1}.$$ 

The form

$$\alpha^j_K \mu^j_{j_1} \land \cdots \land \mu^j_{j_p} \land \eta^j_{K,1} \land \cdots \land \eta^j_{K,n}$$

is an Orlik-Solomon form on $C^j_I$. We extend it by zero to other components of $\bigcup_I C^j_I$.

If $|K| = e(j)$, we define the form $\omega^j_K$ on $\bigcup_I C^j_I$ as the $S_k$-skew-symmetrization of the form

$$\kappa^{-k} \alpha^j_K \mu^j_{j_1} \land \cdots \land \mu^j_{j_p} \land \eta^j_{K,1} \land \cdots \land \eta^j_{K,n}.$$ 

If $|K| = e(j) - 1$, we define the from $\omega^j_K$ on $\bigcup_I C^j_I$ as the $S_k$-skew-symmetrization of the form

$$(-1)^{k-p} \kappa^{-k} \alpha^j_K \mu^j_{j_1} \land \cdots \land \mu^j_{j_p} \land \eta^j_{K,1} \land \cdots \land \eta^j_{K,n}.$$ 

Denote by $A^* (\bigcup_I C^j_I) \subset \bigoplus_I A^* (C^j_I)$ the skew-symmetric part of the Orlik-Solomon space $\bigoplus_I A^* (C^j_I)$ of $\bigcup_I C^j_I$. Recall the 1-form $\omega_a$ in (7.1). The form $\omega_a$ lifts to an element $\tilde{\omega}_a = \pi^* \omega_a$ of $\bigoplus_I A^1 (C^j_I)$ which is symmetric with respect to the $S_k$ action. The exterior multiplication by $\tilde{\omega}_a$ defines the complex

$$(7.2) \quad \land \tilde{\omega}_a : A^{-p-1}_k (\bigcup_I C^j_I) \longrightarrow A^{-p}_k (\bigcup_I C^j_I).$$ 

Recall the vector $m^j = (m^j_1, \ldots, m^j_n)$ from Section 7.4.

**Lemma 7.5.** — The complex in (7.2) is isomorphic to the weight component of weight $|m| - 2k$ of the complex $n_a \otimes (\bigotimes_{i=1}^n M_{m^j_i})^* \rightarrow (\bigotimes_{i=1}^n M_{m^j_i})^*$, see (6.1). The isomorphism sends $\omega^j_K$ to $(-1)^p f \otimes \phi^j_m$ if $|K| = e(j) - 1$ and to $\varphi^j_m$ if $|K| = e(j)$.

Lemma 7.5 is a corollary of Lemma 7.3.
7.6. Residues of skew-symmetric forms. — Consider an $S_k$-orbit $\{C^j_1\}$ of connected components of $Z_p \setminus Z_{p+1}$ and an $S_k$-orbit $\{C^j_1\}$ of connected components of $Z_{p+1} \setminus Z_{p+2}$ such that the second orbit lies in the closure of the first orbit. This statement holds if and only if $j < j'$. More precisely, if $j = \{j_1 < \cdots < j_p\}$, then $\tilde{j} = \{j_1 < \cdots < j_q < j_{q+1} < \cdots < j_p\}$ for some $0 \leq q \leq p$.

Consider $\omega_K^j \in A^j_*(\bigcup_I C^j_I)$. Then the residue of $\omega_K^j$ at $\bigcup_I C^j_I$ is an element of $A^j_*(\bigcup_I C^j_I)$. We denote this residue by $\text{res}_j^j \omega_K^j$.

**Lemma 7.6.** — Given $K = (k_1, \ldots, k_n)$, denote $\tilde{K} = (k_1, \ldots, k_{j+1} - m_{j+1} - 1, \ldots, k_n)$.

- If $k_{j+1} \leq m_{j+1} + 1$, then $\text{res}_j^j \omega_K^j = 0$.
- If $k_{j+1} \geq m_{j+1} + 1$, then
  \[
  \text{res}_j^j \omega_K^j = \begin{cases} 
  (-1)^q \omega_K^j & \text{for } |K| = e(j), \\
  (-1)^{q+1} \omega_K^j & \text{for } |K| = e(j) - 1.
  \end{cases}
  \]

**Proof.** — If $k_{j+1} < m_{j+1} + 1$, then the form $\omega_K^j$ is regular on $\bigcup_I C^j_I$ and $\text{res}_j^j \omega_K^j = 0$. If $k_{j+1} \geq m_{j+1} + 1$, then the statement is checked by direct calculation. □

7.7. Skew-symmetric part of Aomoto complex of weighted Orlik-Solomon manifold. — Consider the weighted Orlik-Solomon manifold $(X, D)$ introduced in Section 7.4 and its Aomoto complex $(A^*\langle X, D \rangle, \tilde{\omega}_a + \text{res})$ introduced in Section 5.2. By Theorem 3.2, for generic nonzero $\kappa$ the complex $(A^*\langle X, D \rangle, \tilde{\omega}_a + \text{res})$ calculates the cohomology $H^*(X, \mathcal{L}_a)$ of $X$ with coefficients in the rank 1 local system $\mathcal{L}_a$ on $X$ associated with the differential form $\tilde{\omega}_a$, see Corollary 3.3.

The group $S_k$ acts on the complex. Denote $(A^*\langle X, D \rangle, \tilde{\omega}_a + \text{res})$ the skew-symmetric part of the complex. For generic nonzero $\kappa$ the complex $(A^*\langle X, D \rangle, \tilde{\omega}_a + \text{res})$ calculates the skew-symmetric part $H^*_s(X, \mathcal{L}_a)$ of the cohomology $H^*(X, \mathcal{L}_a)$.

Recall the complex $(B^*_{m}(|m| - 2k), \tilde{d})$ in Section 6.4. Define the linear map

\[
\gamma : A^*\langle X, D \rangle \longrightarrow B^*_{m}(|m| - 2k),
\]

(7.3)

\[
\omega_K^j \longrightarrow \begin{cases} 
 f \otimes \varphi^K_{m,i} & \text{if } |K| = e(j) - 1, \\
 \varphi^K_{m,i} & \text{if } |K| = e(j).
\end{cases}
\]

**Theorem 7.7.** — The map $\gamma$ defines an isomorphism between the complexes $(A^*\langle X, D \rangle, \tilde{\omega}_a + \text{res})$ and $(B^*_{m}(|m| - 2k), \tilde{d})$.

**Proof.** — The theorem follows from Lemmas 7.5 and 7.6. □

The quasi-isomorphism $C_\infty(\mathbb{Z}_{\geq 0} \otimes_{\mathbb{Z}} L_{m+1})[|m| - 2k] \rightarrow (B^*_{m}, \tilde{d})[|m| - 2k]$ in (6.5) allows us to identify the cohomology $H^*_s(X, \mathcal{L}_a)$ and the cohomology of the complex.

J.E.P. — M., 2014, tome 1
and the element $\beta^K_{m}$ is mapped to $\beta^K_{m} \varphi^K_{m}$ if $|K| = k - 1$ and the element $f^K v_m$ is mapped to $\beta^K_{m} \varphi^K_{m}$ if $|K| = k$, where

$$\beta^K_m = \prod_{i=1}^{n} k_i! \prod_{\ell=1}^{k_i} (m_i + 1 - \ell).$$

Under the isomorphism of Theorem 7.7, we obtain embeddings

$$n_+ \otimes \bigotimes_{a=1}^{n} L_{m_a}[[m] - 2k] \hookrightarrow A^k(U), \quad f \otimes f^K v_m \mapsto \beta^K_{m} \omega_K,$$

$$\bigotimes_{a=1}^{n} L_{m_a}[[m] - 2k] \hookrightarrow A^k(U), \quad f^K v_m \mapsto \beta^K_{m} \omega_K.$$

The images $\mathcal{F}^{k-1} = \text{span}(\beta^K_{m} \omega_K)_{|K|=k-1} \subset A^{k-1}(U)$ and $\mathcal{F}_k = \text{span}(\beta^K_{m} \omega_K)_{|K|=k} \subset A^k(U)$ of these embeddings are called the subspaces of skew-symmetric flag forms, see [SV91, Var95]. The exterior multiplication by $\omega_a$ gives the complex of skew-symmetric flag forms $\wedge \omega_a : \mathcal{F}^{k-1} \to \mathcal{F}_k$. Now the BGG resolution in (6.5) can be interpreted as the statement that the natural embedding of the complex of skew-symmetric flag forms to the complex $(A^\ast(X, F), \bar{\omega}_a + \text{res})$ is a quasi-isomorphism.

The complex of skew-symmetric flag forms can be characterized as follows.

**Lemma 7.9.** — The vector space $\mathcal{F}^\ast$ is the kernel of the residue map

$$A^\ast(U) \to \bigoplus_{j=1}^{n_0} A^\ast(U) \cup C^0_j.$$

**Proof.** — The lemma follows from Lemma 7.6.
7.9. Cohomology $H^\ast(X, \mathcal{L}_\omega)$ and intersection cohomology. — Let $j : U \to \mathbb{C}^k$ be the canonical embedding. Let $\mathcal{L}_\omega$ be the rank 1 local system on $U$ associated with the form $\omega$, see Section 5.2. Consider the intersection cohomology $H^\ast(\mathbb{C}^k, j_! \mathcal{L}_\omega)$. By [AV12], for generic nonzero real $\kappa$, the intersection cohomology $H^\ast(\mathbb{C}^k, j_! \mathcal{L}_\omega)$ is canonically isomorphic to the cohomology $H^\ast(X, \mathcal{L}_\omega)$ if the following condition A from [AV12] is satisfied.

For $1 \leq j \leq n_0$, consider $\mathbb{C}^{m_j}$ with coordinates $u_1, \ldots, u_{m_j}$. Consider the weighted arrangement in $\mathbb{C}^{m_j}$ consisting of the hyperplanes $u_i = 0$, $u_i - 1 = 0$, $u_i - u_p = 0$ with weights $-m_j/\kappa$ for hyperplanes $u_i = 0$ and weights $2/\kappa$ for hyperplanes $u_i - 1 = 0$ and $u_i - u_p = 0$, cf. Section 7.4. Denote by $U_j \subset \mathbb{C}^{m_j}$ the complement to the union of hyperplanes of the arrangement. Let $\mathcal{L}_j$ be the rank 1 local system on $U_j$ associated with this weighted arrangement, see Section 5.2. The condition A is satisfied if for any $1 \leq j \leq n_0$ we have $H^\ell(U_j, \mathcal{L}_j) = 0$ for $\ell > m_j$. Clearly in this situation condition A is satisfied and $H^\ast(\mathbb{C}^k, j_! \mathcal{L}_\omega)$ is canonically isomorphic to the cohomology $H^\ast(X, \mathcal{L}_\omega)$ by [AV12]. In particular, this implies that for generic nonzero real $\kappa$, the skew-symmetric part $H^\ast(\mathbb{C}^k, j_! \mathcal{L}_\omega)$ of the intersection cohomology $H^\ast(\mathbb{C}^k, j_! \mathcal{L}_\omega)$ is isomorphic to the cohomology of the complex $(\mathcal{A}^\ast(X, \mathcal{Z}), \tilde{\omega}_\kappa + \text{res})$ and, hence, to the cohomology of the complex $C_\ast(n \circ L_{m_j})[|m| - 2k]$, see Section 7.7, cf. [KV06, §6 of Introduction] and [KV06, Cor. 6.11].

7.10. Remark. — In the constructions of Section 7 we may assume that $m = (m_1, \ldots, m_n)$ is a vector with arbitrary complex coordinates instead of being a vector with positive integer coordinates. Then all statements of Section 7 hold. In particular, the same proofs show that in this more general situation the complex $C_\ast(n \circ \bigotimes_{i=1}^n L_{m_i})[|m| - 2k]$ calculates the cohomology $H^\ast(\mathbb{C}^k, j_! \mathcal{L}_\omega)$ as well as the intersection cohomology $H^\ast(\mathbb{C}^k, j_! \mathcal{L}_\omega)$.
