L₁-Penalization in Functional Linear Regression with Subgaussian Design

by Vladimir Koltchinskii & Stanislav Minsker

Abstract. — We study functional regression with random subgaussian design and real-valued response. The focus is on the problems in which the regression function can be well approximated by a functional linear model with the slope function being “sparse” in the sense that it can be represented as a sum of a small number of well separated “spikes”. This can be viewed as an extension of now classical sparse estimation problems to the case of infinite dictionaries. We study an estimator of the regression function based on penalized empirical risk minimization with quadratic loss and the complexity penalty defined in terms of $L₁$-norm (a continuous version of LASSO). The main goal is to introduce several important parameters characterizing sparsity in this class of problems and to prove sharp oracle inequalities showing how the $L₂$-error of the continuous LASSO estimator depends on the underlying sparsity of the problem.

Résumé (Pénalisation $L₁$ en régression fonctionnelle linéaire avec design sous-gaussia) Nous étudions la régression fonctionnelle linéaire avec design sous-gaussiain et la réponse à valeurs réelles. Nous nous concentrons sur les problèmes où la fonction de régression est bien approchée par un modèle fonctionnel linéaire dont la pente est « sparse » dans le sens où elle peut être représentée comme une somme d’un petit nombre de « pics » séparés. Nous pouvons considérer ce problème comme une extension du problème classique d’estimation « sparse » au cas d’un dictionnaire infini. Nous étudions un estimateur de la fonction de régression basé sur la minimisation du risque empirique pénalisé avec une perte quadratique et avec une pénalité de complexité définie en termes de la norme $L₁$ (une version continue du LASSO). L’objectif principal est d’introduire certains paramètres importants qui caractérisent la « sparsité » dans cette classe de problèmes et de prouver des inégalités d’oracle « sparses » montrant comment l’erreur $L₂$ de la version continue du LASSO dépend de la sparsité sous-jacent du problème.

1. Introduction

Let \((X, Y)\) be a random couple defined on a probability space \((\Omega, \Sigma, \mathbb{P})\), where \(X = \{X(t) : t \in T\}\) is a stochastic process with parameter set \(T\) and \(Y\) is a real valued response variable. In what follows, it will be assumed that the process \(X\) is subgaussian. Denote
\[
d_X(s, t) := \sqrt{\text{Var} (X(s) - X(t))}, \quad s, t \in T.
\]
(1.1)
It will be also assumed that the space \(T\) is totally bounded with respect to pseudo-metric \(d_X\) and, moreover, it satisfies Talagrand’s generic chaining conditions ensuring that there exists a version of the process \(X(t), t \in T\) that is a.s. uniformly bounded and \(d_X\)-uniformly continuous. In what follows, we assume that \(X(t), t \in T\) is such a version. Let \(\mu\) be a finite measure on the Borel \(\sigma\)-algebra \(\mathcal{B}_T\) of the pseudometric space \((T, d_X)\).

Consider the following regression model
\[
Y = f_\ast(X) + \xi,
\]
where \(f_\ast(X) = \mathbb{E}(Y|X)\) is the regression function and \(\xi\) is a random noise with \(\mathbb{E}\xi = 0\) and variance \(\text{Var}(\xi) = \sigma^2\) independent of the design variable \(X\). We will be interested in estimating the regression function \(f_\ast(X)\) under an underlying assumption that \(f_\ast(X)\) can be well approximated by a functional linear model (“oracle model”)
\[
f_{\lambda,a}(X) = a + \int_T X(t)\lambda(t)\mu(dt),
\]
where \(\lambda \in L_1(\mu)\) is the “slope” function and \(a \in \mathbb{R}\) is the intercept of the model. More precisely, we will focus on the problems in which the oracle models are “sparse” in the sense that the slope function \(\lambda\) is supported in a relatively small subset \(\text{supp}(\lambda) := \{t \in T : \lambda(t) \neq 0\}\) of parameter space \(T\) such that the set of random variables \(\{X(t) : t \in \text{supp}(\lambda)\}\) can be well approximated by a linear space of a small dimension. Often, \(\lambda\) will be a sum of several “spikes” with disjoint and well separated supports. Such models might be useful in a variety of applications, in particular, in image processing where, in many cases, only sparsely located regions of the image are correlated with the response variable. In what follows, \(\Pi\) denotes the marginal distribution of \(X\) in the space \(C_0(\mu(T; d_X))\) of all uniformly bounded and uniformly continuous functions on \((T; d_X)\), and \(P\) denotes the joint distribution of \((X, Y)\) in
Let \((T, \mathbb{X}) \times \mathbb{R}\). Let \((X_1, Y_1), \ldots, (X_n, Y_n)\) be a sample consisting of \(n\) i.i.d. copies of \((X, Y)\) defined on \((\Omega, \Sigma, \mathbb{P})\). The regression function \(f_\ast\) is to be estimated based on the data \((X_1, Y_1), \ldots, (X_n, Y_n)\). Our estimation method can be seen as a direct extension of (a version of) LASSO to the infinite-dimensional case. Namely, let \(D\) be a convex subset of the space \(L^1(\mu)\) such that \(0 \in D\). Consider the following penalized empirical risk minimization problem:

\[
(\hat{\lambda}_\varepsilon, \hat{a}_\varepsilon) := \arg\min_{\lambda \in D, a \in \mathbb{R}} \left[ \frac{1}{n} \sum_{j=1}^n (Y_j - f_{\lambda, a}(X_j))^2 + \varepsilon \|\lambda\|_1 \right],
\]

where

\[
\|\lambda\|_1 := \|\lambda\|_{L^1(\mu)} = \int_T |\lambda(t)| \mu(dt)
\]

and \(\varepsilon > 0\) is the regularization parameter. The function \(f_{\hat{\lambda}_\varepsilon, \hat{a}_\varepsilon}\) will be used as an estimator of the regression function \(f_\ast\).

When the parameter set \(T\) is finite, (1.2) defines a standard LASSO-estimator of the vector of parameters of linear regression model (see [40]). This estimator is among the most popular in high-dimensional statistics and it has been intensively studied in the recent years (e.g., see [9], [16], [25], [6], [26], [4], [27]; see also the book by Bühlmann and van de Geer [8] for further references).

We will be more interested in the case of uncountable infinite parameter sets \(T\) (functional linear models). In such problems, standard characteristics of finite dictionaries used in the theory of sparse recovery (restricted isometry constants, restricted eigenvalues, etc) are not directly applicable. Our goal will be to develop proper parameters characterizing sparsity in the case of functional models and to prove oracle inequalities for the \(L_2(\Pi)\)-error \(\|f_{\hat{\lambda}_\varepsilon, \hat{a}_\varepsilon} - f_\ast\|^2_{L_2(\Pi)}\) of continuous LASSO-estimator in terms of these sparsity parameters. We concentrate on the case of subgaussian random design (that, of course, includes an important example of Gaussian design processes) since, in this case, we can rely on a number of probabilistic tools from the theory of subgaussian and empirical processes. In particular, we extensively use in the proofs recent generic chaining bounds for empirical processes due to Mendelson [33], [32].

It should be emphasized that there is vast literature on functional regression (see, e.g., [35], [36] and references therein). A commonly used general idea in this literature is to estimate the eigenfunctions of the covariance operator and to project the unknown slope function onto the linear span of the “principal components” corresponding to the largest eigenvalues (see [34], [10] and references therein). Under smoothness assumptions on the slope function, a natural approach to its estimation is to use a regularization penalty (see [14] for construction of estimators based on smoothing splines and [42] for a more general reproducing kernel Hilbert space approach).

The problem studied in our paper is much closer to the theory of sparse estimation in high-dimensional statistics and can be viewed as an extension of this theory to the case of functional models and uncountable dictionaries. Our approach is similar in spirit to [24], [26] where such characteristics as “alignment coefficient” (used below
for functional models) were introduced and studied in the case of finite dictionaries, and [28] which extended some of these results to the case of infinite dictionaries. For a review of some modern methods in functional data processing and their connections to various notions of sparsity, we refer the reader to [21]. A recent paper by James, Wang and Zhu [22] is similar to the present work in terms of motivation and approach, however, the theoretical analysis in [22] is performed under the assumptions on the design distribution that might not hold if $X$ has smooth trajectories.

It is important to note that in practice we never observe the whole trajectory of $X$ but rather its densely sampled version. In this case, the natural choice for $\mu$ is a uniform measure on the sampling grid, whence (1.2) becomes the usual LASSO once again. However, there is often no reasons to assume that Gram matrix of the design satisfies RIP [13] or restricted eigenvalue type conditions [6, 23] in this case. Although LASSO might not perform well as a variable selection procedure in such a framework, we will provide examples showing that prediction power of an estimator can still benefit from the fact that the underlying model is (approximately) sparse. In particular, oracle inequalities with error rates depending on sparsity can be derived from the general results of our paper. Other interesting approaches to theoretical analysis of LASSO with highly correlated design were proposed in [17], [19]. For instance, in [17] (see, in particular, Corollary 4.2) the authors show that in the case of highly correlated design, it is often possible to choose the regularization parameter to be small $\varepsilon \ll n^{-1/2}$ and achieve reasonable error rates.

It should be also mentioned that in a number of very important applications one has to deal with sparse recovery in infinite dictionaries with random designs that are not subgaussian, or with deterministic designs. For instance, in [12], the authors develop a theory of super-resolution. In this case, the dictionary consists of complex exponentials $e^{i\langle t, \cdot \rangle}$, $t \in \mathbb{T} \subset \mathbb{R}^d$, the design is deterministic and the estimation method is based on minimizing the total variation norm of a signed measure $\Lambda$ on $\mathbb{T}$ subject to data dependent constraints. Although the results of our paper do not apply immediately to such problems, it is possible to extend our approach in this direction.

We will introduce several assumptions and definitions used throughout the paper.

**Definition 1.1.** — A closed linear subspace $\mathcal{L} \subset L_2(\mathbb{P})$ will be called a subgaussian space if there exists a constant $\Gamma > 0$ such that for all $\eta \in \mathcal{L}$

$$\mathbb{E} e^{s\eta} \leq e^{\Gamma s^2 \sigma^2_\eta}, \quad s \in \mathbb{R},$$

where $\sigma^2_\eta := \text{Var}(\eta)$.

It is well known that $\mathbb{E}\eta = 0, \eta \in \mathcal{L}$ and that $\psi_2$-and $L_2$-norms are equivalent on $\mathcal{L}$ (more precisely, they are within a constant $\sim \Gamma$). Also, if $\mathcal{L}$ is a closed linear subspace of $L_2(\mathbb{P})$ such that $\{\eta : \eta \in \mathcal{L}\}$ are jointly normal centered random variables, then $\mathcal{L}$ is a subgaussian space with $\Gamma = 1$. Another example is the closed linear span of independent centered subgaussian random variables $\{\eta_j\}$ such that

$$\mathbb{E} e^{s\eta_j} \leq e^{\Gamma \sigma^2_\eta s^2}, \quad s \in \mathbb{R}, \quad j \geq 1.$$
for some $\Gamma > 0$:
\[ \mathcal{L} := \left\{ \sum_{j \geq 1} c_j \eta_j : \sum_{j \geq 1} \sigma_{c_j}^2 < +\infty \right\}. \]

For instance, one can consider a sequence $\{\eta_j\}$ of i.i.d. Rademacher random variables (that is, $\eta_j$ takes valued $+1$ and $-1$ with probability $1/2$). In the case of a single random variable $\eta_j$, its linear span is a subgaussian space if and only if $\eta$ is subgaussian.

In what follows, a subgaussian space $\mathcal{L}$ and constant $\Gamma$ will be fixed. All the constants depending only on $\Gamma$ will be called absolute.

**Assumption 1.1.** — Suppose that
\[ X(t) - \mathbb{E}X(t) \in \mathcal{L} \quad \text{for all } t \in T. \]

Denote by $\mathcal{L}_X$ the closed (in $L_2$ and, as a consequence, also in the $\psi_2$-norm) linear span of $\{X(t) - \mathbb{E}X(t) : t \in T\}$.

This assumption easily implies that the stochastic process $Z(t) := X(t) - \mathbb{E}X(t)$, $t \in T$, is subgaussian, meaning the for all $t, s \in T$, $Z(t) - Z(s)$ is a subgaussian random variable with parameter $\Gamma d_X^2(t, s)$.

Next, we recall the notion of Talagrand’s generic chaining complexity (see [39] for a comprehensive introduction). Given a pseudo-metric space $(T, d_X)$, let $\{\Delta_n\}$ be a nested sequence of partitions such that $\text{Card} \Delta_0 = 1$ and $\text{Card} \Delta_n \leq 2^{2^n}$. For $s \in T$, let $\Delta_n(s)$ be the unique subset of $\Delta_n$ containing $s$. The generic chaining complexity $\gamma_2(T; d_X)$ is defined as
\[ \gamma_2(T; d_X) := \inf_{\{\Delta_n\} \in \mathcal{T}} \sup_{t \in T} \sum_{n \geq 0} 2^n D(\Delta_n(s)), \]
where $D(A)$ stands for the diameter of a set $A$. Let
\[ \gamma_2(\delta) := \gamma_2(T; d_X; \delta) = \inf_{\{\Delta_n\} \in \mathcal{T}} \sup_{t \in T} \sum_{n \geq 0} 2^{n/2} (D(\Delta_n(t)) \wedge \delta). \]

If $d_Y$ is another metric on $T$ such that $d_Y(t, s) \leq d_X(t, s)$ for all $t, s \in T$, and $\sup_{t, s \in T} d_Y(t, s) \leq \delta$, then clearly
\[ \gamma_2(T; d_Y) \leq \gamma_2(\delta). \]

This bound will be often used below. Our main complexity assumptions on the design distribution are the following:

**Assumption 1.2.** — Pseudometric space $(T, d_X)$ is such that $\gamma_2(T; d_X) < \infty$ and, moreover,
\[ \gamma_2(T; d_X; \delta) \longrightarrow 0 \quad \text{as } \delta \longrightarrow 0. \]

Under these assumptions, the process $Z = X - \mathbb{E}X$ has a version that is uniformly bounded and $d_X$-uniformly continuous a.s. Moreover, $\|X - \mathbb{E}X\|_{\psi_2} < \infty$ (in particular, all the moments of $\|X - \mathbb{E}X\|_{\psi_2}$ are finite). It what follows, we will denote
\[ S(T) := S(T, d_X) = \inf_{t \in T} \sqrt{\text{Var}(X(t))} + L \gamma_2(T; d_X). \]
Note that Theorem A.2 implies that there exists a numerical constant $L > 0$ such that
\begin{equation}
\mathbb{E} \sup_{t \in T} |X(t) - \mathbb{E}X(t)| \leq S(T).
\end{equation}

We will also need the following assumptions on the regression function $f_*$ and the noise $\xi$:

**Assumption 1.3.** — Suppose that $f_*(X) - \mathbb{E}f_*(X) \in L$ and $\xi \in L$.

Since $\mathbb{E}f_*(X) = \mathbb{E}Y$, this assumption also implies that $Y - \mathbb{E}Y \in L$. Note that if $\{X(t), \ t \in \mathbb{T}\} \cup \{Y\}$ is a family of centered Gaussian random variables and $L$ is its closed linear span, then $L$ is a subgaussian space and $f_*(X)$ is the orthogonal projection of $Y$ onto the subspace $L_X$. Thus, $f_*(X) \in L_X \subset L$.

**Acknowledgements.** — We want to thank the anonymous Referees for carefully reading the paper and for providing constructive feedback that helped us to improve the quality of results and presentation.

The authors are very thankful to Mikhail Lifshits and Mauro Maggioni for insightful discussions and their valuable input.

2. **Approximation error bounds, alignment coefficient and Sobolev norms**

Recall that $P$ is the joint distribution of $(X,Y)$ and let $P_n$ be the empirical distribution based on the sample $(X_1,Y_1), \ldots, (X_n,Y_n)$. The integrals with respect to $P$ and $P_n$ are denoted by
\[
P g := \mathbb{E}g(X,Y), \quad P_n g := \frac{1}{n} \sum_{i=1}^n g(X_i,Y_i).
\]
In what follows, it will be convenient to denote $\ell(y,u) := (y-u)^2$, $y,u \in \mathbb{R}$ and
\[
(\ell \cdot f)(x,y) := \ell(y,f(x)) = (y - f(x))^2.
\]
We also use the notation $\ell'(y,u)$ for the derivative of quadratic loss $\ell(y,u)$ with respect to $u$ : $\ell'(y,u) = 2(u - y)$. Throughout the paper, $\langle \cdot, \cdot \rangle$ denotes the bilinear form
\[
\langle f, g \rangle := \int_{\mathbb{T}} f(t)g(t)\mu(dt).
\]
Let
\[
F_n(\lambda, a) := P_n(\ell \cdot f_{\lambda,a}) + \varepsilon \|\lambda\|_1, \quad F(\lambda, a) := P(\ell \cdot f_{\lambda,a}) + \varepsilon \|\lambda\|_1.
\]
Denote also
\[
\overline{Y}_n := n^{-1} \sum_{j=1}^n Y_j, \quad \overline{X}_n(t) := n^{-1} \sum_{j=1}^n X_j(t), \quad t \in \mathbb{T}.
\]
Note that
\[
\hat{a}(\lambda) := \arg\min_{a \in \mathbb{R}} F_n(\lambda, a) = \overline{Y}_n - \langle \lambda, \overline{X}_n \rangle,
\]
\[
a(\lambda) := \arg\min_{a \in \mathbb{R}} F(\lambda, a) = \mathbb{E}Y - \langle \lambda, \mathbb{E}X \rangle.
\]
The following penalized empirical risk minimization problem
\[
(\hat{\lambda}_\varepsilon, \hat{a}_\varepsilon) := \arg\min_{\lambda \in D, a \in \mathbb{R}} F_n(\lambda; a)
\]
is exactly problem (1.2) written in a more concise form. Note that (2.2) is the empirical version of
\[
(\lambda_\varepsilon, a_\varepsilon) := \arg\min_{\lambda \in \mathbb{D}, a \in \mathbb{R}} F(\lambda, a).
\]
Due to convexity of the loss, both (2.3) and (2.2) are convex optimization problems. It will be shown (Theorem A.1 in the appendix) that, under certain assumptions, they admit (not necessarily unique) solutions \(\lambda_\varepsilon, \hat{\lambda}_\varepsilon\).

Assumption 2.1. — It is assumed throughout the paper that the solutions \((\lambda_\varepsilon, a_\varepsilon)\) of (2.3) and \((\hat{\lambda}_\varepsilon, \hat{a}_\varepsilon)\) of (2.2) exist.

It might be also possible to study the problem under an assumption that \((\lambda_\varepsilon, a_\varepsilon)\) and \((\hat{\lambda}_\varepsilon, \hat{a}_\varepsilon)\) are approximate solutions of the corresponding optimization problems, but we are not pursuing this to avoid further technicalities.

The goal of this section is to determine the parameters responsible for the size of the \(L^2(\Pi)\) risk of \(f_{\lambda_\varepsilon, a_\varepsilon}\), where \((\lambda_\varepsilon, a_\varepsilon)\) is the (distribution-dependent) solution of the problem (2.3), and to find upper bounds on these parameters in terms of classical Sobolev type norms. Later on, it will be shown that the same parameters affect the error rate of empirical solution \(\hat{f}_{\lambda_\varepsilon, a_\varepsilon}\).

Recall that \(\mathbb{D} \subset L^1(\mu)\) is a convex subset that contains zero. It immediately follows from (2.3) that we can take \(a_\varepsilon = a(\lambda_\varepsilon)\) and also that
\[
\|\lambda_\varepsilon\|_1 \leq q(\varepsilon) \varepsilon.
\]
We will be interested, however, in other bounds on \(\|\lambda_\varepsilon\|_1\), in which the “regularization error” is proportional to \(\varepsilon^2\) rather than to \(\varepsilon\) (as it is the case in the bounds for \(q(\varepsilon)\)). To this end, we have to introduce some new characteristics of the oracles \(\lambda \in \mathbb{D}\).
Let $k(s,t) := \text{Cov}(X(s), X(t))$, $s,t \in \mathbb{T}$ be the covariance function of the stochastic process $X$. Clearly, under Assumption 1.2, $\int \int k^2(s,t)\mu(ds)\mu(dt) < \infty$ and the covariance operator $K : L_2(\mathbb{T}, \mu) \to L_2(\mathbb{T}, \mu)$ defined by

$$(Kv)(s) := \int_{\mathbb{T}} k(s,t)v(t)\mu(dt).$$

is Hilbert–Schmidt. For $u \in L_2(\mathbb{T})$, define

$$\|u\|_K := \sup_{(Kv,v) \leq 1} \langle u, v \rangle.$$

**Remark 2.1.** In the case when $\mathbb{T}$ is finite, operator $K$ is represented by the Gram matrix of a finite dictionary and standard “restricted isometry” and “restricted eigenvalue” type constants are defined in terms of $K$ and are involved in oracle inequalities for LASSO and other related estimators.

Note that $\langle Kv, v \rangle = \text{Var}(f_v(X))$, where $f_v(X) := \int_{\mathbb{T}} v(t)X(t)\mu(dt)$. The set

$$\mathbb{H}(K) := \{u \in L_2(\mathbb{T}) : \|u\|_K < \infty\}$$

is a reproducing kernel Hilbert space of the covariance kernel $k$.

We will need the following description of the subdifferential of the convex function $\|\cdot\|_1$:

$$\partial \|\lambda\|_1 = \{w : \mathbb{T} \mapsto [-1,1] : \mu - \text{a.s.} w(t) = \text{sign}(\lambda(t)) \text{ whenever } \lambda(t) \neq 0\}.$$

It follows from the general description of the subdifferential of a norm $\|\cdot\|$ in a Banach space $X$:

$$\partial \|x\| = \begin{cases}\{x^* \in X^* : \|x^*\| = 1, x^*(x) = \|x\|\}, & x \neq 0, \\
\{x^* \in X^* : \|x^*\| \leq 1\}, & x = 0,\end{cases}$$

where $X^*$ is the dual space. For details on our specific example, see [20, §4.5.1].

Note that, in standard examples (such as $\mathbb{T} \subseteq \mathbb{R}^d$), the “canonical” version of the subgradient of $\|\lambda\|_1$, $w(t) := \text{sign}(\lambda(t))$, $t \in \mathbb{T}$, lacks smoothness and RKHS-norms are often large or infinite for such a choice of $w$. It will be seen below that existence of smoother versions of the subgradient is important in such cases. Given a measurable $w : \mathbb{T} \mapsto [-1,1]$, let $T_w = \{t \in \mathbb{T} : |w(t)| \geq 1/2\}$. For smooth $w$, $T_w$ will play a role of support of $\lambda$. Given $b \in [0, \infty]$, define the cone $C_w^{(b)}$ by

$$C_w^{(b)} := \left\{u \in L_1(\mu) : \int_{\mathbb{T} \setminus T_w} |u|d\mu \leq b \langle w, u \rangle \right\}.$$

Note that, for $w \in \partial \|\lambda\|_1$, we have $|w(t)| \leq 1$, $t \in \mathbb{T}$. Therefore, $u \in C_w^{(b)}$ implies that

$$\int_{\mathbb{T} \setminus T_w} |u|d\mu \leq b \int_{T_w} |u|d\mu.$$

Roughly, this means that, for functions $u \in C_w^{(b)}$, $T_w$ is a “dominant set.” Let

$$a_w^{(b)} := \sup \left\{\langle w, u \rangle : u \in C_w^{(b)}, \|f_u\|_{L_2(\Pi)} = 1\right\}.$$
Theorem 2.1. — The following inequality holds:

\[ \| f_{\lambda, a} - f_* \|_{L_2(\Omega)}^2 \leq \inf_{a \in \mathbb{R}} \left[ \| f_{\lambda, a} - f_* \|_{L_2(\Omega)}^2 + \frac{1}{4} \varepsilon^2 \alpha^2(w) \right]. \]

Remark 2.2. — It easily follows from the proof of this theorem that for all \( \lambda \in \mathbb{D} \), \( w \in \partial |\lambda|_1 \), \( a \in \mathbb{R} \),

\[ \int_{T \setminus T_w} |\lambda| \, d\mu \leq \frac{4}{\varepsilon} \left[ \| f_{\lambda, a} - f_* \|_{L_2(\Omega)}^2 + \frac{1}{4} \varepsilon^2 \alpha^2(w) \right]. \]

The intuition behind these results is the following: if there exists an oracle \((\lambda, w, a)\) with a small approximation error \( \| f_{\lambda, a} - f_* \|_{L_2(\Omega)}^2 \) (say, of the order \( o(\varepsilon) \)) and not very large alignment coefficient \( \alpha(w) \), then the risk \( \| f_{\lambda, a} - f_* \|_{L_2(\Omega)}^2 \) is also small and \( \lambda \in \mathbb{D} \) is “almost” concentrated on the set \( T_w \).

As we show below, in some cases \( \| \cdot \|_K \) and \( \alpha(\cdot) \) can be bounded in terms of Sobolev-type norms.

Since self-adjoint integral operator \( K \) with kernel \( k \) is Hilbert–Schmidt, it is compact, and the orthogonal complement to its kernel possesses an orthonormal system of eigenfunctions \( \{ f_j \}_{j=1}^{\infty} \subset L_2(\mathbb{T}, \mu) \) corresponding to positive eigenvalues \( \nu_j \). It is well-known that

\[ H(K) = \left\{ w(\cdot) = \sum_{j=1}^{\infty} w_j f_j(\cdot) : \| w \|_K^2 = \sum_{j=1}^{\infty} w_j^2 / \nu_j < \infty \right\}. \]

However, one might want to find a more direct characterization of \( H(K) \). One way to proceed is to use the so-called Factorization theorem:
Theorem 2.2 ([30], Theorem 4 in Section 9). — Assume that there exists a Hilbert space $\mathcal{V}$ and an injective linear operator $L : \mathcal{V} \mapsto \ell_\infty(\mathbb{T})$ such that $K = LL^*$, where $L^*$ is the adjoint of $L$. Then $\mathbb{H}(K) = L(\mathcal{V})$, and $(L u_1, L u_2)_{\mathbb{H}(K)} = \langle u_1, u_2 \rangle_\mathcal{V}$.

The most obvious choice is $\mathcal{V} = \ker(K)^\perp$ and $L = K^{1/2}$, whence $\|w\|_K = \|K^{-1/2}w\|_{L_2(\mu)}$ which again gives (2.10). Other choices often lead to more insightful description. For example, if $X$ is the standard Brownian motion on $[0,1]$, then one can check [30] that $\mathcal{V} = L_2[0,1]$ with the standard Lebesgue measure and $(Lx)(t) := \int_0^t x(s)ds$ satisfy the requirements. It immediately implies

Corollary 2.1. — The reproducing kernel Hilbert space associated with the Brownian motion is defined by

$$\mathcal{H}(K) = \left\{ h \in L_2[0,1], h(0) = 0, \|h\|_K^2 := \int_0^1 (h'(s))^2 ds < \infty \right\} \subset \mathcal{W}^{2,1}[0,1],$$

where

$$\mathcal{W}^{2,1}[0,1] = \left\{ h \in L_2[0,1], h \text{ is abs. continuous}, \|h\|_{\mathcal{W}^{2,1}}^2 := \int_0^1 [h^2(s) + (h'(s))^2] ds < \infty \right\}$$

is the Sobolev space.

In particular, it means that $a(w) \leq \|w\|_{\mathcal{W}^{2,1}}$. Suppose now that $\mathcal{T} \subset \mathbb{R}^m$ is a bounded open subset and, for some $C > 0$ and $\beta > 0$,

$$a^2(w) \leq C \|w\|^2_{\mathcal{W}^{2,\beta}}. \tag{2.12}$$

Let $\lambda \in L_1(\mathcal{T}, \mu)$ be a “sparse” oracle such that $\text{supp}(\lambda) := \bigcup_{j=1}^d \mathcal{T}_j$, where $\mathcal{T}_j$, $j = 1, \ldots, d$, are disjoint sets. Moreover, assume that the distance between $\mathcal{T}_j$ and $\mathcal{T}_k$ is positive for all $j \neq k$. In other words, $\lambda$ has $d$ components with well separated supports and it is zero in between. In this case, one can find $w \in \partial\|\lambda\|_1$ such that $w = \sum_{j=1}^d w_j$ and $w_j$, $j = 1, \ldots, d$, are smooth functions (from the space $\mathcal{W}^{2,\beta}$ to be specific) with disjoint supports. For any such function $w$, we have

$$a^2(w) \leq C \|w\|^2_{\mathcal{W}^{2,\beta}} \leq C_1 \sum_{j=1}^d \|w_j\|^2_{\mathcal{W}^{2,\beta}} \leq C_1 d \max_{1 \leq j \leq d} \|w_j\|^2_{\mathcal{W}^{2,\beta}}$$

and the bound of Theorem 2.1 implies that

$$\|f_{\lambda, a} - f_{\lambda, a}\|_{L_2(\Pi)}^2 \leq \|f_{\lambda, a}(\lambda) - f_{\lambda, a}\|_{L_2(\Pi)}^2 + C \frac{d}{4} \max_{1 \leq j \leq d} \|w_j\|^2_{\mathcal{W}^{2,\beta}} \varepsilon^2. \tag{2.13}$$

Thus, the size of the error explicitly depends on the number $d$ of components of “sparse” oracles $\lambda$ approximating the target.

In Section 4, we will show that bound (2.12) holds for a number of stochastic processes $X$ and, moreover, there are other ways to take advantage of sparsity in the cases when the domain $\mathcal{T}$ of $X$ can be partitioned in a number of regions $\mathcal{T}_j$, $j = 1, \ldots, N$, such that the processes $\{X(t), t \in \mathcal{T}_j\}$ are “weakly correlated”. 

J.E.P. — M., 2014, tome 1
3. Basic oracle inequalities

In this section, we present general oracle inequalities for the $L_2$-risk of estimator $f_{\hat{\lambda}, \hat{a}}$. The main goal is to show that if there exists an oracle $(\lambda, w, a)$, $\lambda \in \mathbb{D}$, $w \in \partial \|\lambda\|_1$, $a \in \mathbb{R}$ such that the approximation error $\|f_{\lambda,a} - f_*\|_{L_2(\Pi)}^2$ is small, the alignment coefficient $a(w)$ is not large and $\lambda$ is “sparse” in the sense that the set of random variables $\{X(t) : t \in T_w\}$ can be well approximated by a linear space $L \subset \mathcal{L}_X$ of small dimension, then the $L_2$-error $\|f_{\hat{\lambda}, \hat{a}} - f_*\|_{L_2(\Pi)}^2$ of the estimator $f_{\hat{\lambda}, \hat{a}}$ can be controlled in terms of the dimension of $L$ and the alignment coefficient $a(w)$. To state the result precisely, we have to introduce one more parameter, an “approximate dimension”, providing an optimal choice of approximating space $L$ of small dimension, then the approximability of $\{X(t) : t \in T_w\}$ introduced below.

We start, however, with a “slow-rate” oracle inequality that does not depend on “sparsity”. The inequalities of this type are well known in the literature on sparse recovery, in particular, for LASSO estimator in the case of finite dictionaries, see [4], [31].

Recall that $\mathbb{D} \subseteq L_1(\mu)$ is a convex set and $0 \in \mathbb{D}$. Recall also the definition of $q(\epsilon)$ (see 2.4) and its properties. Note that

$$\sigma^2_T = \text{Var}(f_*(X)) + \sigma^2 = \|f_* - \Pi f_*\|_{L_2(\Pi)}^2 + \sigma^2. \tag{3.1}$$

Theorem 3.1. — There exist absolute constants $\mathcal{C}, \epsilon$ and $D$ such that the following holds. For any $s \geq 1$ with $\mathfrak{s} := s + 3 \log(\log_2 n + 2) + 3 \leq \epsilon \sqrt{n}/\log n$ and for all $\epsilon$ satisfying

$$\epsilon \geq D \frac{\mathcal{C} Y S(T)}{\sqrt{n}}, \tag{3.2}$$

with probability at least $1 - e^{-s}$

$$\|f_{\hat{\lambda}, \hat{a}} - f_*\|_{L_2(\Pi)}^2 + \frac{3}{4} \|\hat{\lambda}\|_1 \leq \inf_{\lambda \in \mathbb{D}, a \in \mathbb{R}} \left[\|f_{\lambda,a} - f_*\|_{L_2(\Pi)}^2 + \frac{3}{2} \epsilon \|\lambda\|_1\right] + \mathcal{C} \frac{\sigma^2 \mathfrak{s}}{n}. \tag{3.3}$$

As was mentioned earlier, our main goal is to obtain sharper bounds which would demonstrate connections between the risk of $f_{\hat{\lambda}, \hat{a}}$ and the degree of sparsity of an underlying model. Our next result is a step in this direction. We will need the notion of Kolmogorov’s $d$-width of the set of random variables $C \subset \mathcal{L}_X$ defined as follows:

$$\rho_d(C) := \inf_{L \in \mathcal{L}_X} \sup_{\dim(L) \leq d} \|P_{L^\perp} \eta\|_{L_2(\nu)}.$$

It characterizes the optimal accuracy of approximation of the set $C$ by $d$-dimensional linear subspaces of $\mathcal{L}_X$. Given $T' \subset T$, let

$$X_{T'} := \{X(t) - EX(t) : t \in T'\}.$$

Recall that $T_w := \{t \in T : |w(t)| \geq 1/2\}$. Given an oracle $\lambda \in \mathbb{D}$ and $w \in \partial \|\lambda\|_1$, let

$$\rho_d(w) := \rho_d(X_{T_w}).$$
The following number will play a role of approximate dimension of the set of random variables $X_T$:

$$d(w, \lambda) := \min \left\{ d \geq 0 : \frac{d\sigma^2}{n} \geq \|\lambda\|_1 \frac{\gamma_2 (\rho_d(w))}{\sqrt{n}} \right\}. \tag{3.4}$$

**Theorem 3.2.** — There exist absolute constants $C, \epsilon$ and $D$ such that the following holds. For any $s \geq 1$ with $s := s + 3 \log(\log_2 n + 2) + 3 \leq \epsilon \sqrt{n}/\log n$ and for all $\varepsilon$ satisfying

$$\varepsilon \geq D \frac{\sigma_Y S(T) \sqrt{s}}{\sqrt{n}}, \tag{3.5}$$

with probability at least $1 - e^{-s}$

$$\|f_{\hat{\lambda}, \hat{a}} - f_*\|_{L^2(\Pi)}^2 \leq \inf_{\lambda \in \mathbb{D}} \left[ \|f_{\lambda, a} - f_*\|_{L^2(\Pi)}^2 + 2\varepsilon^2 a^2(w) + C \frac{\sigma^2}{n} \frac{d(w, \lambda)}{\sqrt{n}} \right] + C \frac{\sigma^2}{n}. \tag{3.6}$$

Under an additional assumption that $\|\lambda\|_1$ is not too large, it is possible to prove the following modified version of Theorem 3.2 without the term $C \|\lambda\|_1$ in the oracle inequality.

**Theorem 3.3.** — Assume that conditions of Theorem 3.2 hold. If $\mathbb{D}$ is such that

$$\mathbb{D} \subset \left\{ \lambda \in L_1(\mu) : \|\lambda\|_1 \leq \frac{c\sigma_Y \sqrt{n}}{S(T)} \right\}$$

for some absolute constant $c > 0$, then with probability $\geq 1 - e^{-s}$

$$\|f_{\hat{\lambda}, \hat{a}} - f_*\|_{L^2(\Pi)}^2 \leq \inf_{\lambda \in \mathbb{D}, w \in \partial \|\lambda\|_1} \left[ \|f_{\lambda, a} - f_*\|_{L^2(\Pi)}^2 + 2\varepsilon^2 a^2(w) + C \frac{\sigma^2}{n} \frac{d(w, \lambda)}{\sqrt{n}} \right] + C \frac{\sigma^2}{n}. \tag{3.7}$$

The proof of this result follows from the proof of Theorem 3.2, see remark 7.1 for more details.

**Remark 3.1.** — Note that the oracle inequality of Theorem 3.2 is sharp, meaning that the constant in front of $\|f_{\lambda, a} - f_*\|_{L^2(\Pi)}$ (the leading constant) is 1. It is possible to derive an oracle inequality with the leading constant larger than 1 which might yield faster rates when the variance of the noise $\sigma^2$ is small. Define the following version of the “approximate dimension” (compare to (3.4)):

$$d_{\sigma}(w, \lambda) := \min \left\{ d \geq 0 : \frac{d\sigma^2}{n} \geq \|\lambda\|_1 \frac{\gamma_2 (\rho_d(w))}{\sqrt{n}} \right\}. \tag{3.8}$$
Then, under the assumptions of Theorem 3.2, the following inequality holds with probability \( \geq 1 - e^\epsilon \):

\[
\|f_{\lambda, \theta} - f_{\tau}\|_{L^2(\Omega)}^2 \\
\leq \inf_{\lambda \in \mathbb{D}, \theta \in \partial \|\lambda\|_1, w \in \mathbb{R}} \left[ 2 \|f_{\lambda, \theta} - f_{\tau}\|_{L^2(\Omega)}^2 + 2e^2 \|f_{\lambda, \theta}\|_{L^2(\Omega)} + C \frac{\|\lambda\|_1^2 \|S(\lambda, \theta)\|}{n} + C \frac{\sigma^2}{n} \right].
\]

The proof of this result uses arguments similar to the proof of Theorem 3.2, so we omit the details.

Inequality (3.6) above depends on rather abstract parameters (such as the alignment coefficient and the approximate dimension) that have to be further bounded before one can get a meaningful bound in concrete examples. This will be discussed in some detail in the following sections.

4. Bounding the alignment coefficient

First, we discuss the bounds on the alignment coefficient in terms of Sobolev-type norms in some detail. After this, we turn to the problem of bounding the alignment coefficient in the cases when there exists a weakly correlated partition for the design process \( X \).

4.1. Sacks-Ylvisaker conditions. — In the univariate case \( \mathbb{T} = [0, 1] \), it is possible to determine whether (a certain subspace of) the Sobolev space can be continuously embedded into \( H(K) \) based on the smoothness of the covariance function \( k(\cdot, \cdot) \). Existence of such an embedding is given by the so-called Sacks-Ylvisaker conditions [38]. This provides a way to bound the RKHS norm \( \|\cdot\|_K \) generated by the covariance function of \( X \) (and, thus, also the alignment coefficient) in terms of a Sobolev norm. Definitions and statements below are taken from [37], Section 3.

Set \( \Omega_+ := \{(s, t) \in (0, 1)^2 : s > t\} \) and \( \Omega_- := \{(s, t) \in (0, 1)^2 : s < t\} \). Let \( G \) be a continuous function on \( \Omega_+ \cup \Omega_- \) such that the restrictions \( G|_{\Omega_j} \) are continuously extendable to the closures \( cl(\Omega_j), j \in \{+, -, \} \). \( G_j \) will stand for the extension of \( G \) to \([0, 1]^2\) which is continuous on \( cl(\Omega_j) \) and on \([0, 1]^2 \setminus cl(\Omega_j)\). Set \( R^{(k, j)}(s, t) = \frac{\partial^{k+1}}{\partial s^{k+1}} R(s, t) \). Then, the covariance kernel \( k(\cdot, \cdot) \) defined on \([0, 1]^2\) satisfies the Sacks-Ylvisaker conditions of order \( r \in \mathbb{N} \) if the following holds true:

(A) \( k \in C^{r}\cdot[0, 1]^2\), the partial derivatives of \( G = k^{(r, r)} \) up to order 2 are continuous on \( \Omega_+ \cup \Omega_- \) and are continuously extendable to \( cl(\Omega_+) \) and to \( cl(\Omega_-) \).

(B) \( \inf_{0 \leq \ell \leq 1} \left( G^{(1, 0)}_-(t, t) - G^{(1, 0)}_+(t, t) \right) > 0 \).

(C) \( G^{(2, 0)}_+(t, \cdot) \) belongs to the RKHS with reproducing kernel \( G \) and

\[
\sup_{t \in [0, 1]} \|G^{(2, 0)}_+(t, \cdot)\| < \infty.
\]

(D) In the case \( r \geq 1 \), \( k^{(0, j)}(\cdot, 0) = 0 \) for \( 0 \leq j \leq r - 1 \).
Let $\mathcal{W}^{2,r+1}_0$ be the subspace of $\mathcal{W}^{2,r+1}$ defined by
$$\mathcal{W}^{2,r+1}_0 = \{ f \in \mathcal{W}^{2,r+1} : f^{(j)}(0) = f^{(j)}(1) = 0 \text{ for } 0 \leq j \leq r \}.$$

**Theorem 4.1** (Corollary 1 in [37]). — Assume $k(\cdot, \cdot)$ satisfies the Sacks-Ylvisaker conditions of order $r$. Then $\mathcal{W}^{2,r+1}_0 \subset \mathcal{H}(K)$ and the embedding $\mathcal{W}^{2,r+1}_0 \hookrightarrow \mathcal{H}(K)$ is continuous.

As a result, we have the bound $\|w\|_K \leq C\|w\|_{\mathcal{W}^{2,r+1}}$ that holds for all $w$ with some constant $C > 0$.

It is well-known that the covariance function $k_1(s,t) = s \land t$ of the Brownian motion and $k_2(s,t) = e^{-|s-t|}$ of the Ornstein-Uhlenbeck process satisfy Sacks-Ylvisaker conditions of order $r = 0$.

**Corollary 4.1.** — Let $X(t), t \in [0,1]$ be the Ornstein-Uhlenbeck process and let $\mathcal{H}(K)$ be the associated reproducing kernel Hilbert space. If $w \in \mathcal{W}^{2,1}[0,1]$ is such that $w(0) = w(1) = 0$, then $w \in \mathcal{H}(K)$ and
$$\|w\|_K \leq C\|w\|_{\mathcal{W}^{2,1}[0,1]}.$$

This should be compared to the exact description of $\mathcal{H}(K)$, the kernel of the Ornstein-Uhlenbeck process, which is known to be
$$\mathcal{H}(K) = \left\{ w \in L^2[0,1] : \|w\|_K^2 = \frac{w^2(0) + w^2(1)}{2} + \frac{1}{4} \int_0^1 w^2(t) dt + \int_0^1 (w'(t))^2 dt < \infty \right\}.$$

4.2. **Discrete Sobolev norms and the Brownian motion.** — In this example, we look back at the case when the design process is a Brownian motion (it was already discussed in Section 2). However, this time we make the more realistic assumption that the design processes are observed only at discrete points.

Assume that $\{X(t), t \in [0,1]\}$ is a standard Brownian motion released at zero, that is, $X(t) = Z + W(t)$, where $Z$ is a standard normal random variable independent of $W$. Suppose that we observe $n$ iid copies of $X, X_1, \ldots, X_n$ on a grid $T = \mathcal{G}_N = \{0 \leq t_1 < \cdots < t_N \leq 1\}$. Let $\mu$ be a counting measure on $T$. If, for example, the grid is uniform with mesh size $1/N$ for some large $N$, with high probability the adjacent columns of the design matrix $(X_i(t_j))_{i \leq n, j \leq N}$ will be almost collinear. To the best of our knowledge, a direct analysis based on the restricted eigenvalue type conditions [6] provides unsatisfactory bounds in such cases. On the other hand, results that hold true without any assumptions on the design (e.g., [27], first statement of Theorem 1) only guarantee “slow” rates of convergence (of order $n^{-1/2}$, where $n$ is the size of a training data set).

The covariance function $k(\cdot, \cdot)$ of $X$ satisfies $k(t_i, t_j) = 1 + t_i \land t_j$. Let $K = (1 + t_i \land t_j)_{1 \leq i,j \leq N}$ be the associated Gram matrix and let $K = LL^T$ be its Cholesky
factorization. Note that
\[
L = \begin{pmatrix}
\sqrt{1 + t_1} & 0 & \ldots & 0 \\
\sqrt{1 + t_1} & \sqrt{t_2 - t_1} & 0 & \vdots \\
\vdots & \ddots & \ddots & 0 \\
\sqrt{1 + t_1} & \sqrt{t_2 - t_1} & \ldots & \sqrt{t_N - t_{N-1}}
\end{pmatrix}
\]
By the Factorization theorem (or a straightforward argument), for any \( w \in \mathbb{R}^N \),
\[\|w\|_K = \|L^{-1}w\|_2.\] If \( w = Lv \), then a direct computation shows
\[
(4.1) \quad \|v\|_2^2 = \|w\|_K^2 = \frac{w_1^2}{1 + t_1} + \sum_{j=2}^{N} \frac{(w_j - w_{j-1})^2}{t_j - t_{j-1}}.
\]
The latter expression can be seen as a discrete analogue of the Sobolev norm. For example, let the grid \( G_N \) be uniform, that is, \( t_j = (j-1)/N, \) \( j = 1 \ldots N \), and let \( \lambda : G_N \rightarrow \mathbb{R} \) be sparse in the following sense: \( \text{supp}(\lambda) = \{t_{11} < t_{i_2} < \cdots < t_{i_s}\} \) so that \( |\text{supp}(\lambda)| = s \) and
\[
\min_{2 \leq k \leq s} |t_{ik} - t_{ik-1}| = \sigma \gg \frac{1}{N}.
\]
It is clear from (4.1) that \( \inf_{w \in \partial||\lambda||} \|w\|_K \leq C\sqrt{s/\sigma} \) for some absolute constant \( C > 0 \) (e.g., take a vector whose entries linearly interpolate the sign pattern of \( \lambda \)) while the trivial choice \( w(t_j) = \text{sign}(\lambda(t_j)) \) leads to \( \|w\|_K \geq c\sqrt{Ns} \).

Note also that if \( w_j := w(t_j), \) \( j = 1, \ldots, N, \) for a smooth function \( w \in \mathbb{W}^{2,1}(\mathbb{R}) \), (with a slight abuse of notation, we write \( w \) both for the vector in \( \mathbb{R}^N \) and for the function), then, by Cauchy-Schwarz inequality,
\[
\frac{(w_j - w_{j-1})^2}{t_j - t_{j-1}} = \frac{(w(t_j) - w(t_{j-1}))^2}{t_j - t_{j-1}} = \left( \int_{t_{j-1}}^{t_j} w'(s)ds \right)^2 \leq \int_{t_{j-1}}^{t_j} |w'(s)|^2ds.
\]
It immediately implies that \( \|w\|_K^2 \leq |w(0)|^2 + \int_0^1 |w'(s)|^2ds, \) so the discrete Sobolev norm needed to control the alignment coefficient is bounded from above by its continuous counterpart. As a matter of fact, we have that
\[
\|w\|_K^2 \leq \inf_{\tilde{w}} \left[ |\tilde{w}(0)|^2 + \int_0^1 |\tilde{w}'(s)|^2ds \right],
\]
where the infimum is taken over all functions \( \tilde{w} \in \mathbb{W}^{2,1}([0,1]) \) such that \( \tilde{w}(t_j) = w_j, \) \( j = 1, \ldots, N. \)

These observations allow one to characterize the prediction performance of the LASSO estimator in terms of \( s \) and \( \sigma \), in particular, rates faster than \( n^{-1/2} \) can be deduced from Theorem 3.2.

4.3. Stationary processes. — In this subsection, we derive Sobolev norm bounds on the alignment coefficient in the case when \( X \) is a stationary process (or a stationary random field).
Let $T \subset \mathbb{R}^d$ be a bounded open set and let $\mu$ be the Lebesgue measure. Consider a stationary random field $\{X(t), \ t \in \mathbb{R}^d\}$ with continuous covariance function $k$:
\[ k(t - s) = \text{Cov}(X(t), X(s)), \ t, s \in \mathbb{R}^d. \]
By Bochner’s theorem, there exists a finite Borel measure $\nu$ such that
\[ k(t) = \int_{\mathbb{R}^d} e^{i\langle t, u \rangle} \nu(du), \ t \in \mathbb{R}^d \]
called the spectral measure of $X$. In what follows, we assume that $\nu$ is absolutely continuous with spectral density $v : \mathbb{R}^d \mapsto \mathbb{R}_+^+$.

**Proposition 4.1.** — Suppose that
\[ v(t) \geq \frac{c}{(1 + |t|^2)^p}, \ t \in \mathbb{R}^d \]
for some $p > d/2$ and $c > 0$. For $w$ defined on $T$, let
\[ \Omega(w) := \{ \tilde{w} : \mathbb{R}^d \mapsto \mathbb{R} : \tilde{w}(t) = w(t), \ t \in T \}. \]
Then
\[ \|w\|_K \leq C \inf_{\tilde{w} \in \Omega(w)} \|\tilde{w}\|_{W^{2,p}(\mathbb{R}^d)}. \]

Note that condition (4.3) could not hold for $p \leq d/2$ since this would contradict integrability of the spectral density $v$.

**Proof.** — Given $u \in L_1(\mathbb{R}^d) \cap L_2(\mathbb{R}^d)$, let $\hat{u}$ be its Fourier transform. Observe that
\[ \text{Var}(f_u(X)) = \iint k(t - s)u(t)u(s)dtds = \int |\hat{u}(z)|^2 v(z)dz. \]
For $u$ supported in $T$ and $\tilde{w} \in \Omega(w)$, this gives
\[ \langle w, u \rangle_{L_2(T, \mu)} = \langle \hat{w}, \hat{u} \rangle_{L_2(\mathbb{R}^d)} = \langle \hat{w}, \sqrt{v} \sqrt{\hat{u}} \rangle_{L_2(\mathbb{R}^d)} \leq C \left\| (1 + |x|^2)^{p/2} \hat{w} \right\|_{L_2(\mathbb{R}^d)} \text{Var}(f_u(X)), \]
hence $\|w\|_K \leq C \left\| (1 + |x|^2)^{p/2} \hat{w} \right\|_{L_2(\mathbb{R}^d)}$. It remains to note that by the properties of Fourier transform
\[ \left\| (1 + |x|^2)^{p/2} \hat{w} \right\|_{L_2(\mathbb{R}^d)} \leq C \|\hat{w}\|_{W^{2,p}(\mathbb{R}^d)}. \]

We now turn to the case of stationary processes observed at discrete points. Let $\{X(t), \ t \in \mathbb{R}^d\}$ be a (weakly) stationary random field, and let $X_1, \ldots, X_n$ be i.i.d. copies of $X$ observed on the grid $T = \mathcal{G}_N = \{t_j = 2\pi j/N, \ j \in \{1, \ldots, N\} \}^d$ for some even $N$. In this case, functions on $T$ can be identified with vectors in $\mathbb{R}^{N_d}$. We also assume that $\mu$ is the counting measure on $T$. 

J.É.P. — M., 2014, tome 1
Assumption 4.1. — Suppose the following condition on the spectral density \( v \) of the process \( X \) holds:
\[
(4.4) \quad c_1 \left( \frac{1}{1 + |t|^2} \right)^p \leq v(t) \leq c_2 \left( \frac{1}{1 + |t|^2} \right)^p \quad \text{for some } p > \frac{d}{2},
\]
where \( 0 < c_1 \leq c_2 < \infty \).

Proposition 4.2. — Given \( \bar{w} = (w_1, \ldots, w_N)^T \in \partial \|\lambda\|_1 \), let
\[
\Omega_N(\bar{w}) = \left\{ w \in \mathbb{R}^{2p}(\mathbb{R}^d) : w(2\pi j/N) = w_j, \; j \in \mathbb{Z}^d \right\},
\]
where \( w_j \) are defined arbitrarily for \( j \notin \{1, \ldots, N\}^d \). Under the above-stated assumptions,
\[
\|\bar{w}\|_K \leq C \inf_{w \in \Omega_N(\bar{w})} \|w\|_{\mathbb{R}^{2p}(\mathbb{R}^d)}.
\]

The proof is outlined in section 7.5. Implications of this result for the risk of \( \hat{\lambda}_X \) are presented in Theorem 6.3 below. In particular, we show that rates faster than \( n^{-1/2} \) are often possible.

4.4. Sparse multiple linear models and weakly correlated partitions. — In this section, we assume that
\[
(4.5) \quad Y = a + \sum_{j=1}^N \int_{T_j} X^{(j)}(t_j)d\Lambda_j(t_j) + \xi,
\]
where \( a \in \mathbb{R}, T_1, \ldots, T_N \) are measurable spaces equipped with \( \sigma \)-algebras \( \mathcal{B}_1, \ldots, \mathcal{B}_N \) and finite measures \( \mu_1, \ldots, \mu_N, X^{(1)}, \ldots, X^{(N)} \) are subgaussian stochastic processes on \( T_1, \ldots, T_N, \Lambda_1, \ldots, \Lambda_N \) are signed measures on spaces \( T_1, \ldots, T_N \) with bounded total variations, and \( \xi \) is a zero-mean random variable independent of \( X^{(1)}, \ldots, X^{(N)} \).

Suppose \( \mathcal{B}_j = \mathcal{B}_{T_j} \) (Borel \( \sigma \)-algebra in the semimetric space \( (T_j, d_X) \)). Without loss of generality, we can assume that the sets \( T_1, \ldots, T_N \) form a partition of the space \( T := \bigcup_{j=1}^N T_j \) equipped with a \( \sigma \)-algebra \( \mathcal{B} \) and a measure \( \mu \) such that the measures \( \mu_j \) are restrictions of \( \mu \) on \( T_j \). Similarly, signed measures \( \Lambda_j \) become restrictions on \( T_j \) of a signed measure \( \Lambda_\ast \) on \( (T, \mathcal{B}) \). We will set \( X(t) := X^{(j)}(t), \; t \in T_j, \; j = 1, \ldots, N \), and, finally, we can assume that \( \mathcal{B} = \mathcal{B}_T \) is the Borel \( \sigma \)-algebra in the semimetric space \( (T, d_X) \).

We are interested in the situation when the processes \( \{X^{(j)}(t), \; t \in T_j\}, \; j = 1, \ldots, N \), are weakly correlated (in particular, they can be independent). The number of predictors \( N \) can be very large, but \( Y \) might depend only on \( X^{(j)}(t), \; t \in T_j, \; j \in J \subset \{1, \ldots, N\} \), where \( \text{Card}(J) \ll N \), whence \( \text{Card}(J) \) naturally represents the degree of sparsity of the problem. Another interpretation of the model is to assume that the domain \( T \) of the stochastic process \( X \) can be partitioned in disjoint sets \( T_j \) so that \( \{X(t) : t \in T_j\}, \; j = 1, \ldots, N \), are “weakly correlated”, but only few of the elements of partition are correlated with the response variable \( Y \). It is important to emphasize that the results of the following sections concerning the estimator (1.2) are adaptive with respect to the partitions, in particular, we do not need to know the
we can conclude that 

\[ \sum_{j \in J} \langle w_j, u_j \rangle \leq \sum_{j \in J} \|w_j\|_{K_j} \|f_{u_j}\|_{L_2(\Pi)} \leq \max_{j \in J} \|w_j\|_{K_j} \sum_{j \in J} \|f_{u_j}\|_{L_2(\Pi)}, \]

we can conclude that

\[ \sum_{j \in J} \|f_{u_j}\|_{L_2(\Pi)} \leq b \max_{1 \leq j \leq N} \|k_j\|_\infty \max_{j \in J} \|w_j\|_{K_j} \sum_{j \in J} \|f_{u_j}\|_{L_2(\Pi)} \cdot \]
We proved that $C_w^{(b)} \subseteq C_{\gamma, J}$ for $\gamma := b \max_{1 \leq j \leq N} \|k_j\|_1^{1/2} \max_{j \in J} \|w_j\|_{K_j}$. For all $w \in C_w^{(b)} \subseteq C_{\gamma, J}$, we have
\[
\langle w, u \rangle = \sum_{j \in J} \langle w_j, u_j \rangle \leq \left( \sum_{j \in J} \|w_j\|_{K_j}^2 \right)^{1/2} \left( \sum_{j \in J} \|f_{u_j}\|_{L_2(\Pi)} \right)^{1/2} \leq \beta_2^{(\gamma)}(J) \left( \sum_{j \in J} \|w_j\|_{K_j}^2 \right)^{1/2} \|f_u\|_{L_2(\Pi)},
\]
implying that
\[
a^{(b)}(w) \leq \beta_2^{(\gamma)}(J) \left( \sum_{j \in J} \|w_j\|_{K_j}^2 \right)^{1/2}
\]
with $\gamma := b \max_{1 \leq j \leq N} \|k_j\|_1^{1/2} \max_{j \in J} \|w_j\|_{K_j}$. \hfill \Box

Next, we will relate $\beta_2^{(\gamma)}(J)$ to the size of restricted isometry [13] constants associated with partition $\mathbb{T}_1, \ldots, \mathbb{T}_N$. Given an integer $d \geq 1$, we define the restricted isometry constant $\delta_d$ as the smallest $\delta > 0$ with the following property: for any $J \subset \{1, \ldots, N\}$ with $\text{Card}(J) = d$, any $u_j, j \in J$ such that $\text{supp}(u_j) \subseteq \mathbb{T}_j$ and $\text{Var}(f_{u_j}(X)) = 1$, the spectrum of the $d \times d$ matrix $(\text{Cov}(f_{u_i}(X), f_{u_j}(X)))_{i,j \in J}$ belongs to $[1 - \delta, 1 + \delta]$.

**Proposition 4.4.** — The following inequality holds for all $J \subset \{1, \ldots, N\}$ with $\text{Card}(J) \leq d$:
\[
\beta_2^{(\gamma)}(J) \leq \frac{1 + \delta_{2d}}{(1 - \delta_{2d})^2 - \gamma \delta_{3d}}.
\]

In particular, it means that $\beta_2^{(\gamma)}$ can be bounded by a constant as soon as $\delta_{3d} < 1/(2 + \gamma)$.

**Proof.** — The argument is similar to Lemma 7.2 in [26], the details are included in Appendix A.6 for the reader’s convenience. \hfill \Box

### 5. Oracle inequalities and weakly correlated partitions

First, we will state a corollary of Theorem 3.2 concerning the model of weakly correlated partitions discussed in Section 4. Let $\Delta := \{\mathbb{T}_1, \ldots, \mathbb{T}_N\}$ be a partition of the parameter space $\mathbb{T}$ into $N \geq 1$ measurable disjoint sets. Let $\mathcal{F}$ be the set of all such partitions. Let $X^{(j)}$ denote the restriction of stochastic process $X$ to the set $\mathbb{T}_j$ and let $K_j$ be the covariance operator of the process $X_j$ and $k_j$ be its covariance function. Consider an oracle $\lambda \in L_1(\mu)$ and denote
\[
J_\lambda := \{j = 1, \ldots, N : \mathbb{T}_j \cap \text{supp}(\lambda) \neq \emptyset\}.
\]
Also, denote $N(\lambda) := \text{Card}(J_\lambda)$. Usually, we assume that $N$ is very large and $N(\lambda)$ is much smaller than $N$, so, $N(\lambda)$ plays the role of “sparsity parameter” in this framework. Let $w = \sum_{j \in J_\lambda} w_j \in \partial \|\lambda\|_1$ be a subgradient such that $\text{supp}(w_j) \subset \mathbb{T}_j$. 

J. E. P. — M., 2014, tome 1
In what follows, denote \( \mathcal{W}_{\lambda, \Delta} \) the set of all such subgradients \( w \). Recall the definition of the quantity \( \beta_2^{(\gamma)}(J) \) (Section 4) and denote

\[
\beta(w, \lambda) := \beta_2^{(\gamma)}(J_\lambda), \quad \gamma := 16 \max_{1 \leq j \leq N} \| k_j \|_{\infty}^{1/2} \max_{j \in J_\lambda} \| w_j \|_{K_j}.
\]

Proposition 4.3 implies that

\[
a(w) \leq \beta(w, \lambda) \left( \sum_{j \in J_\lambda} \| w_j \|^2_{K_j} \right)^{1/2}.
\]

We will also need the following quantities that would play the role of “approximate dimensions” of the sets of random variables \( X_{T_{w_j}}, j \in J \) (local versions of \( d(w, \lambda) \)):

\[
d_j(w, \lambda) := \min \left\{ m \geq 0 : \frac{m \sigma_Y^2}{n} \geq \| \lambda \|_1 \frac{\gamma_2 (\rho_m(w_j))}{\sqrt{n}} \right\},
\]

Proposition 5.1. — Under the above notations, the following bound holds:

\[
d(w, \lambda) \leq \sum_{j \in J_\lambda} d_j(w, \lambda).
\]

Proof. — Denote \( m_j := d_j(w, \lambda) \). Then,

\[
\frac{m_j \sigma_Y^2}{n} \geq \| \lambda \|_1 \frac{\gamma_2 (\rho_m(w_j))}{\sqrt{n}}, \quad j \in J_\lambda
\]

and, for all \( j \in J_\lambda \) and \( \delta > 0 \), there exist \( L_j \subset \mathcal{L}_X \) such that \( \text{dim}(L_j) \leq m_j \) and

\[
\sup_{t \in T_{w_j}} \| P_{L_j}^\perp (X(t) - E X(t)) \|_{L^2(\Pi)} \leq \rho_{m_j}(w_j) + \delta.
\]

Denote \( L := \text{l.s.}(\bigcup_{j \in J_\lambda} L_j) \). Then,

\[
\sup_{t \in T_{w}} \| P_{L}^\perp (X(t) - E X(t)) \|_{L^2(\Pi)} \leq \max_{j \in J_\lambda} \sup_{t \in T_{w_j}} \| P_{L_j}^\perp (X(t) - E X(t)) \|_{L^2(\Pi)} \]

\[
\leq \max_{j \in J_\lambda} \rho_{m_j}(w_j) + \delta
\]

and

\[
\frac{\sigma_Y^2}{n} \sum_{j \in J_\lambda} m_j \geq \| \lambda \|_1 \frac{\gamma_2 (\max_{j \in J_\lambda} \rho_{m_j}(w_j))}{\sqrt{n}}.
\]

Since \( \text{dim}(L) \leq \sum_{j \in J_\lambda} m_j := m \), we have

\[
\rho_m(w) \leq \sup_{t \in T_{w}} \| P_{L}^\perp (X(t) - E X(t)) \|_{L^2(\Pi)} \leq \max_{j \in J_\lambda} \rho_{m_j}(w_j) + \delta.
\]

It follows that

\[
\frac{\sigma_Y^2 m}{n} \geq \| \lambda \|_1 \frac{\gamma_2 (\rho_m(w) - \delta)}{\sqrt{n}}.
\]

Since \( \delta > 0 \) is arbitrary, this yields

\[
\frac{\sigma_Y^2 m}{n} \geq \| \lambda \|_1 \frac{\gamma_2 (\rho_m(w))}{\sqrt{n}},
\]

and the result follows. \( \square \)

\[\text{J.E.P. - M., 2014, tome 1}\]
As a very simple example, let \( I_1, \ldots, I_N \) be disjoint finite subsets of the set \( \mathbb{N} \) of natural numbers and let
\[
X(t) = X^{(j)}(t) = \sum_{k \in I_j} \eta^{(j)}_k \phi_k(t), \quad t \in \mathbb{T}, \ j = 1, \ldots, N,
\]
where \( \phi_k, k \in I_j \) are bounded measurable functions on \( \mathbb{T} \), \( j = 1, \ldots, N \), and \( \{ \eta^{(j)}_k : k \in I_j, j = 1, \ldots, N \} \) are centered jointly normal random variables. Denote \( m_j := \text{Card}(I_j), j = 1, \ldots, N \). Let \( \lambda \in \mathbb{D} \) and \( w \in \mathcal{W}_\lambda, \Delta \). Obviously,
\[
\delta_j(w, \lambda) \leq m_j, \ j \in J_\lambda,
\]
so, we have a simple bound
\[
d(w, \lambda) \leq \sum_{j \in J_\lambda} m_j.
\]

The next statement immediately follows from Theorem 3.2, Proposition 5.1 and bound (5.1).

**Corollary 5.1.** — Suppose that assumptions and notations of Theorem 3.2 hold. There exists an absolute constant \( \mathcal{C} > 0 \) such that with probability at least \( 1 - e^{-s} \)
\[
\| f_{\lambda, \Delta} - f_* \|_{L_2(\Pi)}^2 \leq \inf_{w \in \mathcal{W}_\lambda, \Delta, a \in \mathbb{R}} \left[ \| f_{\lambda,a} - f_* \|_{L_2(\Pi)}^2 \right.
\]
\[
+ 2e^2 \beta^2 (w, \lambda) \sum_{j \in J_\lambda} \| w_j \|_{K_j}^2 + \mathcal{C} \left( \sum_{j \in J_\lambda} \| \phi_j(w, \lambda) \|_2 \right)^2 + \mathcal{C} \left( \sum_{j \in J_\lambda} \| \phi_j(w, \lambda) \|_2 \right) \frac{\| \Sigma \|_2}{n} \right] + \mathcal{C} \frac{\sigma^2 \Sigma}{n}.
\]

The term \( \| \lambda \|_1^2 \Sigma^2(\mathbb{T})/n \) that depends on \( \| \lambda \|_1^2 \) can be dropped if \( \| \lambda \|_1 \) is not too large (see Theorem 3.3). In general, this term can be controlled in terms of sparsity parameter \( N(\lambda) \) and \( \| \lambda \|_{L_2(\mu)} \). To this end, note that, by Cauchy-Schwarz inequality,
\[
\| \lambda \|_1 = \sum_{j \in J_\lambda} \int_{\mathbb{T}_j} |\lambda| d\mu \leq \sum_{j \in J_\lambda} \left( \int_{\mathbb{T}_j} |\lambda|^2 d\mu \right)^{1/2} \mu^{1/2}(\mathbb{T}_j)
\]
\[
\leq \left( \sum_{j \in J_\lambda} \int_{\mathbb{T}_j} |\lambda|^2 d\mu \right)^{1/2} \left( \sum_{j \in J_\lambda} \mu(\mathbb{T}_j) \right)^{1/2} \leq \| \lambda \|_{L_2(\mu)} \max_{j \in J_\lambda} \mu^{1/2}(\mathbb{T}_j) \sqrt{N(\lambda)}.
\]

For an arbitrary oracle \( \lambda \in \mathbb{T} \), arbitrary partition \( \Delta \in \mathcal{F} \), arbitrary subgradient \( w \in \mathcal{W}_\lambda, \mathcal{F} \) and for
\[
\varepsilon = D \frac{\sigma \sqrt{S(\mathbb{T})}}{\sqrt{n}},
\]
we have the following inequality that holds with probability at least \( 1 - e^{-s} \):
\[
\| f_{\lambda, \Delta} - f_* \|_{L_2(\Pi)}^2 \leq \| f_{\lambda,a(\lambda)} - f_* \|_{L_2(\Pi)}^2 + \mathcal{C} \left[ \Omega(w, \lambda, \Delta) \frac{N(\lambda)}{n} + \frac{\sigma^2 \Sigma}{n} \right],
\]
\[\text{J.E.P - M., 2014, tome 1,}\]
where
\[ \Omega(w, \lambda, \Delta) := \sigma^2 \mathcal{S}(T) \beta^2(w, \lambda) \max_{j \in J} \|w_j\|_{K_j}^2 + \mathcal{D}(w, \lambda) + S^2(T) \|\lambda\|_{L_2(\mu)} \max_{j \in J} \mu(\mathcal{T}_j). \]

Thus, if there is an oracle \( \lambda \in \mathbb{D} \) for which the approximation error \( \|f_{\lambda,a}(\lambda) - f_\star\|_{L_2(\Pi)}^2 \) is small and the quantity \( \Omega(w, \lambda, \Delta) \) is of a moderate size, then the error of the estimator \( (\hat{\lambda}, \hat{a}_\varepsilon) \) is essentially controlled by the quantity \( N(\lambda)/n \) (up to log factors). Since \( N(\lambda) \) can be viewed as a degree of sparsity of the oracle \( \lambda \), this explains the connection of the oracle inequality of Corollary 5.1 and now classical bounds for LASSO in the case of large finite dictionaries. Once again, it is important to emphasize that the estimation method (1.2) does not require any knowledge of a "weakly correlated partition" \( \Delta \). The method is adaptive in the sense that, if there exists a partition \( \Delta \) such that \( \beta(w, \lambda) \) and other quantities involved in the definition of \( \Omega(w, \lambda, \Delta) \) are not large, then the size of the error depends on the degree of sparsity \( N(\lambda) \) with respect to the partition of oracles \( \lambda \) that provide good approximation of the target.

In the simplest example, \( T := \{1, \ldots, N\} \) and the partition \( \Delta := \{\{1\}, \ldots, \{N\}\} \) (so, \( T \) is partitioned in one point sets). Let \( \mu \) be the counting measure. Thus, \( X \) is an \( N \)-dimensional subgaussian vector and we are in the framework of standard high-dimensional multiple regression model. For simplicity, assume that \( X \) is scaled in such a way that \( \mathbb{E}X(t) = 0, \mathbb{E}X^2(t) = 1 \). The estimator (1.2) becomes a version of usual LASSO-estimator. Then, it is easy to check that \( S(T) \leq C \sqrt{\log N} \). Also, in this case RKHS-spaces \( \mathbb{H}(K_j), j = 1, \ldots, N \), are one-dimensional and we have \( \|w_j\|_{K_j} = |w(j)|, j = 1, \ldots, N \). For an oracle \( \lambda \in \mathbb{D} \),

\[ N(\lambda) = \text{Card}(J_\lambda), \quad J_\lambda = \text{supp}(\lambda) = \{1 \leq j \leq N : \lambda_j \neq 0\}. \]

In this case, we can set \( w(j) = \text{sign}(\lambda(j)), j = 1, \ldots, N \). Also, we obviously have \( \mathcal{D}(w, \lambda) = 1 \). Finally, in this case the quantity \( \beta_2(\gamma)(J) \) coincides with standard "cone constrained" characteristics frequently used in the literature on sparse recovery (see, e.g., [26], Section 7.2.2). We will use \( \beta(\lambda) = \beta(w, \lambda) = \beta_2(\gamma)(J_\lambda) \). Then, Corollary 5.1 takes the following form.

**Corollary 5.2.** — There exist absolute constants \( \mathcal{E}, \mathcal{C} \) and \( D \) such that the following holds. For any \( s \geq 1 \) with \( \mathcal{S} := s + 3 \log(\log_2 n + 2) + 3 \leq \sqrt{s}/\sqrt{n} \) and for all \( \varepsilon \) satisfying

\[ \varepsilon \geq D \frac{\mathcal{S} \sqrt{s \log N}}{\sqrt{n}}, \]

with probability at least \( 1 - e^{-s} \)

\[ \|f_{\lambda_{\epsilon}, \hat{a}_\varepsilon} - f_\star\|_{L_2(\Pi)}^2 \leq \inf_{\lambda \in \mathbb{D}, a \in \mathbb{R}} \left[ \|f_{\lambda,a} - f_\star\|_{L_2(\Pi)}^2 + 2\beta^2(\lambda)N(\lambda)\varepsilon^2 + \mathcal{E}\frac{\sigma^2 N(\lambda)}{n} + \mathcal{E}\frac{\|\lambda\|_{L_2(\mu)}^2 \log N}{n} \right] + \mathcal{E}\frac{\sigma^2}{n}. \]
More generally, assume that $\mathcal{T}$ is a finite set with a counting measure $\mu$ and consider an arbitrary partition $\Delta = \{T_1, \ldots, T_N\}$ of $\mathcal{T}$. Denote
\[ m_j := \mu(T_j) = \text{Card}(T_j), \quad j = 1, \ldots, N \]
and $m := \mu(\mathcal{T}) = \text{Card}(\mathcal{T})$. As before, $X$ is subgaussian and $EX(t) = 0$, $EX^2(t) = 1$. Then, we have $S(\mathcal{T}) \leq C\sqrt{\log m}$. In this case, covariance operators $K_j$ are acting in $m_j$-dimensional Euclidean spaces and we have
\[ \|w_j\|_{K_j} = \|K_j^{-1/2}w_j\|_2, \quad j = 1, \ldots, N. \]
Clearly, we also have $d_j(w, \lambda) \leq m_j$. Thus, the oracle inequality of Corollary 5.1 implies that
\begin{equation}
\|f_\lambda - f\|_{L^2(\Pi)}^2 \leq \inf_{\lambda \in \mathcal{D}, \Delta \in \mathcal{T}} \left[ \|f_\lambda - f\|_{L^2(\Pi)}^2 \right. \\
+ 2\beta^2(w, \lambda)D_j \left[ \sum_{j \in J} \|K_j^{-1/2}w_j\|_2^2 + \epsilon \sum_{j \in J} \frac{m_j}{n} + \epsilon \frac{m^2 \log m}{n} \right] + \epsilon \epsilon_{1/2},
\end{equation}
This holds with probability at least $1 - e^{-s}$ for all $\epsilon$ satisfying $\epsilon \geq D\sigma \sqrt{s \log m} / \sqrt{n}$.

6. Stationary and piecewise stationary processes

Suppose $\mathcal{T}$ is a bounded subset of $\mathbb{R}^d$ with Lebesgue measure $\mu$ and let $\Delta = \{T_1, \ldots, T_N\}$ be a measurable partition of $\mathcal{T}$.

**Assumption 6.1.** — Suppose that each set $T_j$ is contained in a ball of radius $r$. In what follows, we assume that $r \geq N^{-1/d}$. It is easy to see that there exists a constant $\kappa \geq 2$ depending only on $d$ such that the $\epsilon$-covering numbers of $\mathcal{T}$ with respect to the standard Euclidean distance satisfy the condition
\begin{equation}
N(\mathcal{T}; \epsilon) \leq \left( \frac{R}{\epsilon} \right)^d \sqrt{N}, \quad \epsilon \in (0, R),
\end{equation}
where $R = \kappa N^{1/d}r$.

Let $X^{(j)}$, $j = 1, \ldots, N$, be centered stationary subgaussian processes on $\mathbb{R}^d$ and let
\[ X(t) := \sum_{j=1}^N X^{(j)}(t)\mathbb{I}_{T_j}(t), \quad t \in \mathcal{T}. \]
Thus, we can view the process $X$ as “piecewise stationary”. Let $K_j$ denote the covariance operator and $v_j$ denote the spectral density of $X^{(j)}$, $j = 1, \ldots, N$ (we assume that the spectral densities exist).

**Assumption 6.2.** — Suppose that, for some constant $B > 0$ and some $p > d/2$,
\begin{equation}
\frac{1}{B(1 + |t|^2)^p} \leq v_j(t) \leq B \frac{1}{(1 + |t|^2)^p}, \quad t \in \mathbb{R}^d, \quad j = 1, \ldots, N.
\end{equation}
We use the notations $J_\lambda$, $N(\lambda) = \text{Card}(J_\lambda)$ and $\beta(\lambda) = \beta(w, \lambda)$ introduced in Section 5. Let $\lambda \in D$ be an oracle such that, for each $j \in J_\lambda$ we either have that $\lambda(t) \geq 0$ for all $t \in T_j$, or $\lambda(t) \leq 0$ for all $t \in T_j$. Thus, $\lambda$ does not change its sign inside the elements of the partition. Denote $D_\Delta$ the set of all such oracles in $D$.

Finally, denote $R(\lambda) = \kappa(N(\lambda))^{1/d}$. Clearly, $r \leq R(\lambda) \leq R$ (we assume that $N(\lambda) \geq 1$) and condition (6.1) holds for the covering numbers of the set $\bigcup_{j \in J_\lambda} T_j$ with $R(\lambda)$ in place of $R$.

**Theorem 6.1.** — There exist constants $C, \epsilon$ and $D$ depending only on $B, p, \sigma$ such that the following holds. For any $s \geq 1$ with $\overline{s} := s + 3 \log(\log_2 n + 2) + 3 \leq \epsilon \sqrt{n}/\log n$, for all $\epsilon$ satisfying

$$\epsilon \geq D \frac{\sigma \sqrt{s(\log N \lor \log r)}}{\sqrt{n}},$$

with probability at least $1 - e^{-s}$

(6.3) \[ \| f_{\lambda, \alpha} - f_s \|_{L^2(\Pi)} \leq \inf_{\lambda \in D_\Delta, \alpha \in \mathbb{R}} \left[ \| f_{\lambda, \alpha} - f_s \|_{L^2(\Pi)}^2 + \epsilon \left( \sigma_Y^2 r^{d(1 + r^{-p})} \right)^2 L^{d(2p + d)} \| \lambda \|_{L^1(\Pi)}^{2d(2p + d)} \right] \]

$$+ \epsilon \left( \sigma_Y^2 \right)^2 n \frac{\| \lambda \|_{L^1(\Pi)}^2}{n^{2p/(2p + d)}} + \epsilon \| \lambda \|_{L^1(\Pi)}^{2d(2p + d)} \| \lambda \|_{L^1(\Pi)}^2 \frac{\log N \lor |\log r|}{n},$$

where $L := \log N \lor \log n \lor |\log \sigma_Y| \lor |\log r|$.

We will now consider a stationary subgaussian random field $X(t)$, $t \in \mathbb{R}^d$, observed in a ball $T = \{ t : |t| \leq R \}$ of radius $R \geq 2$.

**Assumption 6.3.** — Suppose that $X$ has a spectral density $v(t)$, $t \in \mathbb{R}^d$ and, for some constant $B > 0$ and some $p > d/2$,

(6.4) \[ \frac{1}{B} \left( 1 + |t|^2 \right)^p \leq v(t) \leq B \left( 1 + |t|^2 \right)^p, \quad t \in \mathbb{R}^d. \]

Let $\lambda \in D$ be an oracle such that $\text{supp}(\lambda)$ can be covered by a union of $N(\lambda)$ disjoint balls $B(t_1; r), \ldots, B(t_{N(\lambda)}; r)$ of radius $r \leq R/2$. Moreover, let us assume that the balls in this covering are well separated in the sense that the distance between any two distinct balls is at least $2r$. In addition to this, assume that $\lambda$ does not change sign on each of the sets $B(t_j; r) \cap \text{supp}(\lambda)$, $j = 1, \ldots, N(\lambda)$. Let $D_r$ denote the set of all such oracles $\lambda \in D$.

Then, the following theorem holds.

**Theorem 6.2.** — There exist constants $C, \epsilon$ and $D$ depending only on $B, p, \sigma$ such that the following holds. For any $s \geq 1$ with $\overline{s} := s + 3 \log(\log_2 n + 2) + 3 \leq \epsilon \sqrt{n}/\log n$, for all $\epsilon$ satisfying

$$\epsilon \geq D \frac{\sigma \sqrt{s \log R}}{\sqrt{n}},$$

J.É.P. — M., 2014, tome 1
with probability at least $1 - e^{-s}$

\[
(6.5) \quad \|f_{\lambda_*, \tilde{a}_*} - f_*\|_{L_2(\Pi)}^2 \leq \inf_{\lambda \in \mathbb{R}, a \in \mathbb{R}} \left[ \|f_{\lambda, a} - f_*\|_{L_2(\Pi)}^2 \right]
\]

\[
+ \mathcal{C} \left( \sigma_Y^2 r^d \right) \frac{2^{p+d}}{n^{2p/(2p+d)}} L^{d/(2p+d)} \frac{\|\lambda\|_{1}^{2d/(2p+d)} N(\lambda)(2p-d)/(2p+d)}{n^{2p/(2p+d)}}
\]

\[
+ \mathcal{C} \frac{\sigma_Y^2 N(\lambda)}{n} + \mathcal{C} r^d (1 + r^{-p})^2 N(\lambda) \epsilon^2 + \mathcal{C} \frac{\|\lambda\|_{2}^2 \log R}{n} + \mathcal{C} \frac{\sigma_Y^2 \pi}{n},
\]

where $L := \log n \lor \log \sigma_Y \lor \log R \lor \log r$.

Note that in Theorems 6.1 and 6.2 the error rate depends on “sparsity parameter” $N(\lambda)$ (its meaning is somewhat different in these two cases). Moreover, the error rate involves a “nonparametric term” $O(n^{-2p/(2p+d)})$. Thus, $p > d/2$ plays a role of smoothness parameter in this problem.

Often, it is natural to assume that the target function $f_*(X)$ can be approximated by $f_{\lambda}(X)$, where $\Lambda$ is a discrete signed measure supported on a “well-separated” subset of $\mathbb{T}$, so that $f_{\lambda}(X) = \sum_{j=1}^{N(\lambda)} \lambda_j X(t_j)$, where

\[
\min_{1 \leq i < j \leq N(\lambda)} |t_i - t_j| \geq 3\delta(\Lambda) > 0
\]

and $\delta(\Lambda)$ is large enough. Such a discrete oracle $\Lambda$ can be further approximated by a linear combination of continuous “spikes” supported in well separated disjoint balls of radius $r > 0$. This can be done for an arbitrary $r < \delta(\Lambda)$ and optimizing the bound of Theorem 6.2 with respect to $r$ would lead to a bound with a faster error rate. We will implement this in a special (and practically important) case when the design processes $X_j$, $j = 1, \ldots, n$ are observed on a discrete grid in $\mathbb{R}^d$. Specifically, assume that $T = \mathcal{D}_N = \{t_j = 2\pi j/N, \ j \in \{1, \ldots, N\}^d\}$ and it is equipped with the counting measure $\mu$, see section 4.3 for more details. Note that in this case we are in the framework of a standard high-dimensional linear regression with highly correlated design. Functions $\lambda$ on $\mathbb{T}$ can be identified with vectors in $\mathbb{R}^N$ and we will assume that $\mathcal{D} := R^N$. Suppose that Assumption 6.3 holds and let $\lambda$ be an oracle such that $J(\lambda) = \text{supp}(\lambda) \subset \{1, \ldots, N\}^d$, $N(\lambda) := \text{Card}(J(\lambda))$, and

\[
\min_{i,j \in J(\lambda), i \neq j} \frac{|i - j|}{N} =: 2\delta(\lambda) \geq \frac{1}{N},
\]

where $|i - j|$ stands for the usual Euclidean distance in $\mathbb{R}^d$. We are mainly interested in the oracles $\lambda$ with “well-separated” non-zero elements, meaning that $\delta(\lambda) \gg 1/N$.

In this setting, the following result holds.

**Theorem 6.3.** — There exist constants $\mathcal{C}$, $\epsilon$ and $D$ depending only on $B, p, d$ such that the following holds. For any $s \geq 1$ with $\overline{s} := s + 3 \log(\log_2 n + 2) + 3 \leq \sqrt{n}/\log n$, let

\[
\epsilon = D \frac{\sigma_Y \sqrt{s}}{\sqrt{n}}.
\]
Then with probability at least $1 - e^{-s}$
\[
\|f_{\lambda/a} - f_\ast\|^2_{L_2(\Omega)} \leq \inf_{\lambda \in \mathbb{R}, a \in \mathbb{R}} \left[ \|f_{\lambda/a} - f_\ast\|^2_{L_2(\Omega)} + \mathcal{C} \delta_\lambda^{d-2n} \frac{N(\lambda)s}{n} \right. \\
+ \mathcal{C} \sigma_Y^{p/(p+d)} \left( sL\|\lambda\|_1^2 \right)^{d/(2p+2d)} \frac{N(\lambda)^p/(p+d)}{n^{(2p+2d)/(2p+2d)}} + \mathcal{C} \|\lambda\|_1^2 \right] + \mathcal{C} \sigma_Y^2 \frac{s}{n},
\]
where $L = \log n \lor \log N \lor \log \sigma_Y$.

7. Proofs of the main results

7.1. Preliminaries. — Recall that
\[
F_n(\lambda, a) := P_n(\ell \cdot f_{\lambda/a}) + \varepsilon \|\lambda\|_1, \quad F(\lambda, a) := P(\ell \cdot f_{\lambda/a}) + \varepsilon \|\lambda\|_1.
\]
In the proofs of the main results, we will use necessary conditions for the minima in problems (1.2), (2.3) that will be stated now. Given a convex functional $\lambda \in \mathbb{R}^2$, only remains to examine the
\[
\partial \|f\|_1 \ni \{ f \mapsto -\langle f, \lambda \rangle \}.
\]

\begin{proposition}
For any $\lambda_1, \lambda_2 \in \mathbb{D}$ and $a_1, a_2 \in \mathbb{R}$,
\[
DF_n(\lambda_1, a_1)(\lambda_2 - \lambda_1, a_2 - a_1) = P_n(\ell \cdot f_{\lambda_1/a_1}) - f_{\lambda_2/a_2} - f_{\lambda_1/a_1} + \varepsilon \langle w_1, \lambda_2 - \lambda_1 \rangle
\]
for some $w_1 \in \partial \|\lambda\|_1$ that depends on $\lambda_2$. Similarly,
\[
DF(\lambda_1, a_1)(\lambda_2 - \lambda_1, a_2 - a_1) = P(\ell \cdot f_{\lambda_1/a_1}) - f_{\lambda_2/a_2} - f_{\lambda_1/a_1} + \varepsilon \langle w_1, \lambda_2 - \lambda_1 \rangle.
\]
\end{proposition}

Proof. — The treatment of the terms $P_n(\ell \cdot f_{\lambda/a})$, $P(\ell \cdot f_{\lambda/a})$ is straightforward, so it only remains to examine the $L_1$-penalty term. Let $v := \lambda_2 - \lambda_1$. Since the function $(0, 1) \ni s \mapsto |\lambda_1(t) + sv(t)|$ is convex, we have that
\[
(0, 1) \ni s \mapsto \frac{|\lambda_1(t) + sv(t)| - |\lambda_1(t)|}{s}
\]
is nondecreasing. Given a decreasing sequence $\{s_n\}_{n \geq 0} \subset (0, 1)$ such that $s_n \to 0$, the sequence of functions
\[
g_n(t) := \frac{|\lambda_1(t) + s_nv(t)| - |\lambda_1(t)|}{s_n}
\]
monotonically converges to
\[
g(t) = \begin{cases} 
\text{sign}(\lambda_1(t))v(t), & \lambda_1(t) \neq 0 \\
\text{sign}(v(t))v(t), & \text{else}.
\end{cases}
\]
Moreover, $g_n(t)$ are integrable, and the monotone convergence theorem implies that
\[
\lim_{n \to \infty} \int_T g_n d\mu = \int_T g d\mu = \int_T w_1 u d\mu,
\]
where $|w_1(t)| \leq 1$, $t \in T$ and $w_1(t) = \text{sign}(\lambda_1(t))$, $\lambda_1(t) \neq 0$. In particular, $w_1 \in \partial \|\lambda_1\|_1$.

\hfill \Box
When $\lambda_1 = \tilde{\lambda}_e$ (which minimizes $F_\alpha$), the corresponding directional derivatives must be nonnegative for any $\lambda_2 \in \mathbb{D}$.

7.2. Proof of Theorem 2.1. — Let $(\tilde{\lambda}, \mathbf{w}, \pi)$ be a triple that minimizes the right-hand side of (2.9). If the infimum is not attained, one can consider the triple for which the right-hand side is arbitrarily close to the infimum and follow the argument below.

Since $(\lambda_e, a_e)$ minimizes $F(\lambda, a)$ over $\mathbb{D} \times \mathbb{R}$, the directional derivative

$$DF(\lambda_e, a_e)(\tilde{\lambda} - \lambda_e, \pi - a_e)$$

is nonnegative for any $\tilde{\lambda} \in \mathbb{D}$, $\pi \in \mathbb{R}$. By Proposition 7.1, this is equivalent to the following: there exists $w_\varepsilon \in \partial \|\lambda_e\|_1$ such that

$$\langle \ell' \cdot f_{\lambda_e, a_e}, f_{\lambda_e, a_e} - f_{\lambda, \pi} \rangle + \varepsilon \langle w_\varepsilon, \lambda_e - \tilde{\lambda} \rangle \leq 0.$$  

(7.1)

Let $\mathbf{w} \in \partial \|\lambda_e\|_1$. Since

$$\langle \ell' \cdot f_{\lambda_e, a_e}, (x, y) \rangle = 2(\langle f_{\lambda_e, a_e}(x) - y \rangle, \mathbf{w})$$

and also $Y = f_s(X) + \xi$, where $\mathbb{E}(\xi|X) = 0$, we have

$$P(\langle \ell' \cdot f_{\lambda_e, a_e}, (f_{\lambda_e, a_e} - f_{\lambda, \pi}) \rangle = 2\mathbb{E}(f_{\lambda_e, a_e}(X) - Y)(\langle f_{\lambda_e, a_e}(X) - f_{\lambda, \pi}(X) \rangle)$$

$$= 2(\langle f_{\lambda_e, a_e} - f_s, f_{\lambda_e, a_e} - f_{\lambda, \pi} \rangle)_{L_2(\Pi)}.$$  

Thus, (7.1) can be rewritten as

$$2(\langle f_{\lambda_e, a_e} - f_s, f_{\lambda_e, a_e} - f_{\lambda, \pi} \rangle)_{L_2(\Pi)} + \varepsilon \langle w_\varepsilon, \mathbf{w}, \lambda_e - \tilde{\lambda} \rangle \leq \varepsilon \langle \mathbf{w}, \lambda_e - \tilde{\lambda} \rangle.$$  

Note that

$$2(\langle f_{\lambda_e, a_e} - f_s, f_{\lambda_e, a_e} - f_{\lambda, \pi} \rangle)_{L_2(\Pi)} = \|f_{\lambda_e, a_e} - f_s\|_{L_2(\Pi)}^2 + \|f_{\lambda_e, a_e} - f_{\lambda, \pi}\|_{L_2(\Pi)}^2$$

$$- \|f_{\lambda, \pi} - f_s\|_{L_2(\Pi)}^2$$

and

$$\langle w_\varepsilon, \lambda_e - \tilde{\lambda} \rangle \geq \frac{1}{2} \int_{\mathbb{T} \setminus \tilde{\lambda}} |\lambda_e| d\mu.$$  

Hence

$$\|f_{\lambda_e, a_e} - f_s\|_{L_2(\Pi)}^2 + \|f_{\lambda_e, a_e} - f_{\lambda, \pi}\|_{L_2(\Pi)}^2 + \varepsilon \frac{1}{2} \int_{\mathbb{T} \setminus \tilde{\lambda}} |\lambda_e| d\mu$$

$$\leq \|f_{\lambda, \pi} - f_s\|_{L_2(\Pi)}^2 + \varepsilon \langle \mathbf{w}, \lambda_e - \tilde{\lambda} \rangle.$$  

(7.3)

Consider two cases: first, if

$$\|f_{\lambda_e, a_e} - f_s\|_{L_2(\Pi)}^2 + \varepsilon \frac{1}{4} \int_{\mathbb{T} \setminus \tilde{\lambda}} |\lambda_e| d\mu \leq \|f_{\lambda, \pi} - f_s\|_{L_2(\Pi)}^2,$$

then inequality (2.9) clearly holds. Otherwise, (7.3) implies that

$$\int_{\mathbb{T} \setminus \tilde{\lambda}} |\lambda_e| d\mu = \int_{\mathbb{T} \setminus \tilde{\lambda}} |\lambda_e - \tilde{\lambda}| d\mu \leq 4 \langle \mathbf{w}, \lambda_e - \tilde{\lambda} \rangle.$$  

J. É. F. — M., 2014, tome 1
Hence, \( \lambda_e - \overline{X} \in C_\infty^{(4)} \) and
\[
eq (\overline{w}, \lambda_e - \overline{X}) \leq \|f_{\lambda_e, a_e} - f_{\overline{X}, \overline{\pi}}\|_{L_2(\Pi)} a(\overline{w}) \leq \frac{1}{4} \epsilon^2 a^2(\overline{w}) + \|f_{\lambda_e, a_e} - f_{\overline{X}, \overline{\pi}}\|_{L_2(\Pi)}^2,
\]
where we used the definition of \( a(\overline{w}) \) and a simple inequality \( ab \leq \frac{1}{4} a^2 + b^2 \). Substituting this bound into (7.3) gives the result.

7.3. Proof of Theorem 3.2. — Throughout the proof, \( C, C_1, c, c_1, \) etc. denote absolute constants whose values may change from line to line.

**Step 1. Reduction to empirical processes.** — Let \((\overline{X}, \overline{w}, \overline{\pi})\) be a triple that minimizes the right-hand side of bound (3.6). Clearly, \( a = a(\overline{X}) \), see (2.1). If the infimum is not attained, it is easy to modify the argument by considering a triple for which the right-hand side is arbitrarily close to the infimum. Since \( 0 \in \mathbb{D} \) and, for which \( \lambda = 0 \), one can also take \( w = 0 \) and \( a = \mathbb{E} Y = \mathbb{E} f_*(X) \), we have that
\[
(7.4) \quad \|f_{\overline{X}, \overline{\pi}} - f_*\|_{L_2(\Pi)}^2 \leq \|f_* - \Pi f_*\|_{L_2(\Pi)}^2 = \text{Var}(f_*(X))
\]
and
\[
(7.5) \quad \|\overline{X}\|_1^2 \leq \frac{\|f_* - \Pi f_*\|_{L_2(\Pi)}^2}{\mathbb{E}^2(\Pi)}.
\]
We will write in what follows \( \overline{\lambda} = \overline{\lambda}_e \) and set \( \hat{a} := \hat{a}(\overline{\lambda}) \). Since \( (\overline{\lambda}, \hat{a}) \) minimizes \( F_\alpha(\lambda, a) \) over \( \mathbb{D} \times \mathbb{R} \), the directional derivative \( DF_\alpha(\overline{\lambda}, \hat{a})(\overline{X} - \overline{\lambda}, \overline{\pi} - \hat{a}) \) is nonnegative. Here and in what follows, we use the “optimal” value \( \overline{\pi} = a(\overline{X}) \), see (2.1). By Proposition 7.1, this is equivalent to the following: there exists \( \hat{w} \in \partial \|\overline{\lambda}\|_1 \) such that
\[
(7.6) \quad P_n(\ell' \cdot f_{\hat{X}, \hat{a}})(f_{\hat{X}, \hat{a}} - f_{\overline{X}, \overline{\pi}}) + \epsilon(\hat{w}, \overline{X} - \overline{\lambda}) \leq 0.
\]
Since \( \overline{w} \in \partial \|\overline{X}\|_1 \), (7.6) can be rewritten as
\[
(7.7) \quad P(\ell' \cdot f_{\overline{X}, \overline{\pi}})(f_{\overline{X}, \overline{\pi}} - f_{\overline{X}, \overline{\pi}}) + \epsilon(\hat{w} - \overline{w}, \overline{X} - \overline{\lambda}) \\
\leq \epsilon(\overline{w}, \overline{X} - \overline{\lambda}) + (P - P_n)(\ell' \cdot f_{f_{\overline{X}, \overline{\pi}}})(f_{\overline{X}, \overline{\pi}} - f_{\overline{X}, \overline{\pi}}).
\]
Denote \( \eta(x, y) := y - f_{\overline{X}, \overline{\pi}}(x) \). Observe that
\[
(\ell' \cdot f_{f_{\overline{X}, \overline{\pi}}})(x, y) = -2(y - f_{\overline{X}, \overline{\pi}}(x)) = -2\eta(x, y) + 2(f_{\overline{X}, \overline{\pi}}(x) - f_{\overline{X}, \overline{\pi}}(x))
\]
and, since \( Y = f_*(X) + \xi, \mathbb{E}(\xi | X) = 0 \),
\[
- \mathbb{E}(\eta(f_{\overline{X}, \overline{\pi}}) - f_{\overline{X}, \overline{\pi}})) = \mathbb{E}(f_{\overline{X}, \overline{\pi}}(X) - f_{\overline{X}, \overline{\pi}}(X))
\]
\[
= \mathbb{E}(f_{\overline{X}, \overline{\pi}}(X) - f_{\overline{X}, \overline{\pi}}(X)) = (f_{\overline{X}, \overline{\pi}}(x) - f_*(x) - f_{\overline{X}, \overline{\pi}}(x))_L^2(\Pi).
\]
Therefore, we get the following bound:
\[
2(f_{\overline{X}, \overline{\pi}} - f_*, f_{\hat{X}, \hat{a}} - f_{\overline{X}, \overline{\pi}})_L^2(\Pi) + 2\|f_{\hat{X}, \hat{a}} - f_{\overline{X}, \overline{\pi}}\|_{L_2(\Pi)}^2 + \epsilon(\hat{w} - \overline{w}, \overline{X} - \overline{\lambda}) \\
\leq \epsilon(\overline{w}, \overline{X} - \overline{\lambda}) + 2(P_n - P)(f_{\overline{X}, \overline{\pi}} - f_{\overline{X}, \overline{\pi}}) + 2(\Pi - \Pi_n)(f_{\overline{X}, \overline{\pi}} - f_{\overline{X}, \overline{\pi}})^2.
\]
Using the fact that
\[ 2\langle f_{\lambda,\pi} - f_\ast, f_{\lambda,\pi} - f_{\lambda,\pi}\rangle_{L_2(\Pi)} = \|f_{\lambda,\pi} - f_\ast\|^2_{L_2(\Pi)} - \|f_{\lambda,\pi} - f_{\lambda,\pi}\|^2_{L_2(\Pi)} \]

it can be rewritten as
\[ (7.8) \quad \|f_{\lambda,\pi} - f_\ast\|^2_{L_2(\Pi)} + \|f_{\lambda,\pi} - f_{\lambda,\pi}\|^2_{L_2(\Pi)} + \varepsilon\langle \tilde{\omega} - \overline{\omega}, \lambda - \overline{\lambda} \rangle \leq \|f_{\lambda,\pi} - f_\ast\|^2_{L_2(\Pi)} + \varepsilon\langle \overline{\lambda}, \lambda \rangle + 2(P_n - P)\eta(f_{\lambda,\pi} - f_{\lambda,\pi}) + 2(\Pi - \Pi_n)(f_{\lambda,\pi} - f_{\lambda,\pi})^2. \]

The main part of the proof deals with bounding the empirical processes in the right-hand side of (7.8). In what follows, \( L \) denotes a subspace of the subgaussian space \( L_X \subset L_2(\mathbb{P}) \) (the closed linear span of \( \{X(t) - E(X(t)) : t \in T\} \)). Let \( d := \dim(L) \) and let \( P_L, P_{L^\perp} \) be the orthogonal projections onto the subspace \( L \) and its orthogonal complement \( L^\perp \subset L_X \), and
\[ (7.9) \quad \rho := \rho(L) := \sup_{t \in \mathcal{T}_\rho} \|P_{L^\perp}(X(t) - \overline{E}(X(t)))\|_{L_2(\mathbb{P})}. \]

**Step 2. Bounds for** \( P_n - P \)[\( \eta(f_{\lambda,\pi} - f_{\lambda,\pi}) \)]. — Let \( f_\lambda^0(\cdot) := f_{\lambda,\ast}(\cdot) - \Pi f_{\lambda,\ast} \), which clearly satisfies \( \Pi f_\lambda^0 = 0 \). Observe that the following decomposition holds:
\[ (7.10) \quad f_{\lambda,\pi} - f_{\lambda,\pi} = f_\lambda^0 - f_{\lambda,\pi}^0 + \overline{Y}_n - \overline{E}Y + \langle \tilde{\lambda} - \overline{\lambda}, \overline{E}X - \overline{X}_n \rangle. \]

This implies
\[ (P_n - P)\eta(f_{\lambda,\pi} - f_{\lambda,\pi}) = (P_n - P)\eta(f_\lambda^0 - f_{\lambda,\pi}^0) + (P_n - P)\eta(\overline{Y}_n - \overline{E}Y) + (P_n - P)\eta(\Pi_n - \Pi)\eta(\overline{X}_n). \]

Denote
\[ \Lambda(\delta, \Delta, R) := \left\{ \lambda \in \mathbb{D} : \|f_\lambda^0 - f_{\lambda,\pi}^0\|_{L_2(\Pi)} \leq \delta, \int_{\mathcal{T}_\rho} |\lambda||d\mu| \leq \Delta, \|\lambda\|_1 \leq R \right\}, \]
\[ \alpha_n(\delta; \Delta, R) := \sup_{\lambda \in \Lambda(\delta, \Delta, R)} \left| (P_n - P)\eta(f_\lambda^0 - f_{\lambda,\pi}^0) \right|, \]
\[ \tau_n(\delta; \Delta, R) := \sup_{\lambda \in \Lambda(\delta, \Delta, R)} \left| (\Pi_n - \Pi)\eta(f_\lambda^0 - f_{\lambda,\pi}^0) \right|. \]

Then
\[ (7.11) \quad \left| (P_n - P)\eta(f_{\lambda,\pi} - f_{\lambda,\pi}) \right| \leq \alpha_n \left( \|f_\lambda^0 - f_{\lambda,\pi}^0\|_{L_2(\Pi)}, \int_{\mathcal{T}_\rho} |\lambda|d\mu, \|\lambda\|_1 \right) + \|\overline{Y}_n - \overline{E}Y\| \cdot |(P_n - P)\eta| + \alpha_n \left( \|f_\lambda^0 - f_{\lambda,\pi}^0\|_{L_2(\Pi)}, \int_{\mathcal{T}_\rho} |\lambda|d\mu, \|\lambda\|_1 \right) \]
\[ + \|\overline{Y}_n - \overline{E}Y\| \cdot |(P_n - P)\eta| + \left| (P_n - P)\eta \right| \cdot \left| \langle \tilde{\lambda}, \overline{E}X - \overline{X}_n \rangle \right|. \]

To provide upper bounds on each of the terms in the right-hand side of (7.11) we need several lemmas.
Lemma 7.1. — Let \( \{Y(t), t \in \mathbb{T}\} \) be a centered subgaussian process such that
\[
E Y(t)Y(s) = \text{Cov}(X(t), X(s)), \quad t, s \in \mathbb{T}.
\]
There exists a constant \( C > 0 \) such that
\[
E \sup_{\lambda \in \Lambda(\delta, \Delta, R)} |\langle Y, \lambda - \lambda_0 \rangle| \leq C \left[ \delta \sqrt{d} \vee (R + \|\lambda\|_1) \gamma_2(\rho) \vee \Delta S(\mathbb{T}) \right].
\]

Proof. — Denote \( \mathcal{L}_Y \) the closed linear span of \( \{Y(t), t \in \mathbb{T}\} \), the subgaussian space of the process \( Y \). Clearly, the mapping \( X(t) - EX(t) \mapsto Y(t), t \in \mathbb{T} \) can be extended to an \( L_2(\mathcal{P}) \)-isometry of the spaces \( \mathcal{L}_X, \mathcal{L}_Y \subset L_2(\mathcal{P}) \). Let \( \tilde{L} \) be the image of the subspace \( L \) under this isometry. For all \( \lambda \in \Lambda(\delta, \Delta, R) \) and for \( u := \lambda - \lambda_0 \),
\[
\langle Y, u \rangle = P_{\tilde{L}}(Y, u) + \int_{\mathbb{T}} P_{\tilde{L}}(Y(t)u(t)) \mu(dt) + \int_{\mathbb{T} \setminus \mathbb{T}_M} P_{\tilde{L}}(Y(t)u(t)) \mu(dt).
\]

We will use this representation and bound separately the supremum of each term to control
\[
\sup \{ |\langle Y, \lambda - \lambda_0 \rangle| : \lambda \in \Lambda(\delta, \Delta, R) \}.
\]
For the first term, let \( \xi_1, \ldots, \xi_d \) be an orthonormal basis of \( \tilde{L} \). Note that for \( u = \lambda - \lambda_0, \lambda \in \Lambda(\delta, \Delta, R) \), we have \( E(\langle Y, u \rangle)^2 = \|u\|_{L_2(\mathbb{T})}^2 \leq \delta^2 \). Therefore,
\[
E \sup \{ |P_{\tilde{L}}(Y, \lambda - \lambda_0)| : \lambda \in \Lambda(\delta, \Delta, R) \} \leq E \sup \{ |P_{\tilde{L}}(Y, u)| : E(\langle Y, u \rangle)^2 \leq \delta^2 \}
\]
\[
\leq E \sup \left\{ \sum_{k=1}^d \alpha_k \xi_k \right\} \leq \delta E \left( \sum_{k=1}^d \xi_k^2 \right)^{1/2} \leq \delta \sqrt{d}.
\]

For the second term, observe that for \( u = \lambda - \lambda_0, \lambda \in \Lambda(\delta, \Delta, R) \)
\[
\left| \int_{\mathbb{T}} P_{\tilde{L}}(Y(t)u(t)) \mu(dt) \right| \leq \sup_{t \in \mathbb{T}} |P_{\tilde{L}}(Y(t))| \|u\|_1 \leq (R + \|\lambda_0\|_1) \sup_{t \in \mathbb{T}} |P_{\tilde{L}}(Y(t))|.
\]

Denote \( U(t) := P_{\tilde{L}}(Y(t)), t \in \mathbb{T} \). Clearly, \( U \) is a centered subgaussian process such that
\[
E(U(t) - U(s))^2 \leq E(Y(t) - Y(s))^2, \quad t, s \in \mathbb{T}
\]
and, as a consequence, \( \|U(t) - U(s)\|_{L_2} \leq c\|Y(t) - Y(s)\|_{L_2} \) with an absolute constant \( c > 0 \). Moreover, since the spaces \( \mathcal{L}_Y, \tilde{L} \) are isometric images of the spaces \( \mathcal{L}_X, L \), we also have that
\[
\sup_{t \in \mathbb{T}} E(U(t))^2 = \sup_{t \in \mathbb{T}} E|P_{\tilde{L}}(Y(t))|^2 = \sup_{t \in \mathbb{T}} E|P_{\tilde{L}}(X - EX)(t)|^2 = \rho^2,
\]
which implies that \( \sup_{t \in \mathbb{T}} \|U(t)\|_{L_2} \leq cp \). Then, it follows from the upper bound on sup-norms of subgaussian processes in terms of generic chaining complexities (in particular, (1.4)) that
\[
E \sup_{\lambda \in \Lambda(\delta, \Delta, R)} |P_{\tilde{L}}(Y(t))| \leq C \gamma_2(\rho)
\]
and
\[
E \sup_{\lambda \in \Lambda(\delta, \Delta, R)} \left| \int_{\mathbb{T}} P_{\tilde{L}}(Y(t)(\lambda - \lambda_0)(t)) \mu(dt) \right| \leq C(R + \|\lambda_0\|_1) \gamma_2(\rho).
\]
with an absolute constant $C > 0$. Finally, for the third term, note that for $u = \lambda - \overline{X}$, $\lambda \in \Lambda(\delta, \Delta, R)$

$$\int_{T \times T^\perp} P_{L^2} Y(t) u(t) \mu(dt) \leq \sup_{t \in T} |P_{L^2} Y(t)| \int_{T \times T^\perp} |u| d\mu \leq \Delta \sup_{t \in T} |P_{L^2} Y(t)|,$$

where we used the fact that $\overline{X}(t) = 0$, $u(t) = \lambda(t)$ for $t \in T \setminus T_w$. By an argument similar to the one used for the second term of (7.12), we get

$$\mathbb{E} \sup_{\lambda \in \Lambda(\delta, \Delta, R)} \left| \int_{T \times T^\perp} P_{L^2} Y(t)(\lambda - \overline{X})(t) \mu(dt) \right| \leq C \Delta S(T),$$

which implies the bound of the lemma.

**Lemma 7.2.** There exists a constant $C > 0$ such that, for all $\delta > 0, \Delta > 0, R > 0$,

$$\mathbb{E} \alpha_n(\delta, \Delta, R) \leq C \left( \|f_\overline{X} - f_*\|_{L_2(\Pi)} \vee \|\xi\|_{\psi_2} \right) \left[ \delta \sqrt{n} \vee (R \vee \|\overline{X}\|_1) \frac{\gamma_2(\rho)}{\sqrt{n}} \vee \Delta S(T) \right].$$

**Proof:** Let $F := \mathcal{F}(\delta, \Delta, R) := \{ f_\overline{X}^\lambda - f_\overline{X} : \lambda \in \Lambda(\delta, \Delta, R) \}$. We use a recent result by S. Mendelson (see Theorem A.4, statement (i)) which implies that, for all $\delta, \Delta, R$,

$$\mathbb{E} \alpha_n(\delta, \Delta, R) \leq C \left[ \left\| \eta \right\|_{\psi_2} \gamma_2(F; \psi_2) \frac{\sqrt{\gamma_2(F; \psi_2)}}{n} \right][\delta \vee (R \vee \|\Lambda\|_1) \gamma_2(\rho) \vee \Delta S(T)],$$

for an absolute constant $C > 0$. Since $\{ f(X) : f \in \mathcal{F}(\delta, \Delta, R) \} \subset \mathcal{L}$ and $\mathcal{L}$ is a subgaussian space, we have that $\|f\|_{\psi_2} \leq c_1 \|f\|_{L_2(\Pi)}, f \in \mathcal{F}(\delta, \Delta, R)$ for some constant $c_1$. Therefore,

$$\gamma_2(F; \|\|_{\psi_2}) \leq c_2 \gamma_2(F; L_2(\Pi)).$$

Let $G(t), t \in T$ be a centered Gaussian process with the same covariance as the process $\{X(t), t \in T\}$. Then the stochastic processes $u \mapsto \langle G, u \rangle$ has the same covariance as $u \mapsto \langle X - \mathbb{E}X, u \rangle = f_\overline{X}^{(0)}(X)$, that is, $\mathbb{E} \langle G, u_1 \rangle \langle G, u_2 \rangle = \langle f_\overline{X}^{(0)}(X), f_\overline{X}^{(0)}(X) \rangle_{L_2(\Pi)}$. By Talagrand’s generic chaining theorem for Gaussian processes (Theorem 2.1.1 in [39]), this implies

$$\gamma_2(F, L_2(\Pi)) \leq c_2 \mathbb{E} \sup \{ |\langle \langle G, \lambda - \overline{X} \rangle | : \lambda \in \Lambda(\delta, \Delta, R) \}.$$

Using Lemma 7.1, we get the following bound on $\gamma_2(F, \|\|_{\psi_2})$:

$$\gamma_2(F, \|\|_{\psi_2}) \leq C \left[ \delta \vee (R + \|\overline{X}\|_1) \gamma_2(\rho) \vee \Delta S(T) \right].$$

Next, note that

$$\eta(X, Y) = Y - f_\overline{X}(X) = f_\lambda(X) + \xi - f_\overline{X}(X).$$

We also have $\mathbb{E} f_\lambda(X) = \mathbb{E} Y$ and

$$\mathbb{E} f_\overline{X}(X) = \mathbb{E} Y - \langle \overline{X}, \mathbb{E}X \rangle + \mathbb{E} \langle \overline{X}, X \rangle = \mathbb{E} Y$$
which implies that \( \mathbb{E}_\eta(X, Y) = 0 \). The random variable \( f_\ast(X) - f_{\varphi}(X) \) belongs to the subgaussian space \( \mathcal{L} \), implying that

\[
\|\eta\|_{\psi_2} = \|f_\ast(X) - f_{\varphi}(X) + \xi\|_{\psi_2} \leq \|f_\ast(X) - f_{\varphi}(X)\|_{\psi_2} + \|\xi\|_{\psi_2} \leq c\|f_{\varphi}\|_{\mathcal{L}(\Pi)} + \|\xi\|_{\psi_2}
\]

with an absolute constant \( c > 0 \). In view of (7.13), (7.14) and (7.15) easily imply the bound of the lemma.

Our next goal is to derive an upper bound on \( \alpha_n(\delta, \Delta, R) \) that holds uniformly in \( \delta \in [\delta_-, \delta_+] \), \( \Delta \in [\Delta_-, \Delta_+] \), \( R \in [R_-, R_+] \) for some \( \delta_- < \delta_+, \Delta_- < \Delta_+, R_- < R_+ \) to be determined later. Let

\[
J_1 := [\log_2 (\delta_+ / \delta_-)] + 1, \quad J_2 := [\log_2 (\Delta_+ / \Delta_-)] + 1, \quad J_3 := [\log_2 (R_+ / R_-)] + 1
\]

and, given \( s > 0 \), let

\[
\tilde{s} := s + \log \left( (J_1 + 1)(J_2 + 1)(J_3 + 1) \right).
\]

Finally, denote

\[
\nu_n(\delta, \Delta, R) := \inf_{L \subset \mathcal{L}} \left[ \delta \frac{\dim(L)}{n} \sqrt{\frac{\mathbb{V}(R \vee \|X\|_1)}{n}} \| \Delta^{\psi_n} \|_{\psi_2} \right],
\]

where the infimum is taken over all finite dimensional subspaces \( L \subset \mathcal{L} \) and \( \rho(L) \) is defined in (7.9).

**Lemma 7.3.** There exists a constant \( C > 0 \) with the following property. With probability at least \( 1 - e^{-s} \), the following inequality holds uniformly for all \( \delta \in [\delta_-, \delta_+] \), \( \Delta \in [\Delta_-, \Delta_+] \), \( R \in [R_-, R_+] \):\n
\[
\alpha_n(\delta, \Delta, R) \leq C \left( \|f_{\varphi} - f_\ast\|_{\mathcal{L}(\Pi)} \vee \|\xi\|_{\psi_2} \right) \left[ \delta \frac{\tilde{s}}{n} \| \nu_n(\delta, \Delta, R) \|_{\psi_2} \right] \]

\[
\cdot \sqrt{\frac{\mathbb{V}(\mathcal{F}(\delta, \Delta, R))}{n^2}}.
\]

**Proof.** First, we use Adamczak’s version of Talagrand’s inequality (A.7) to deduce an exponential bound on \( \alpha_n(\delta, \Delta, R) \) from the bound on \( \mathbb{E}_{\alpha_n}(\delta, \Delta, R) \) (for fixed \( \delta, \Delta, R > 0 \)). To this end, observe that, by the properties of Orlicz norms and subgaussian spaces,

\[
\left\| \eta(f_\ast^\lambda - f_{\varphi}^\lambda) \right\|_{\mathcal{L}(P)} \leq \left\| \eta \right\|_{\mathcal{L}(P)} \left\| f_\ast^\lambda - f_{\varphi}^\lambda \right\|_{\mathcal{L}_4(\Pi)} \leq c_1 \left\| \eta \right\|_{\psi_2} \left\| f_\ast^\lambda - f_{\varphi}^\lambda \right\|_{\mathcal{L}_4(\Pi)} \leq \left\| f_{\varphi} - f_\ast \right\|_{\mathcal{L}_4(\Pi)} + \left\| f_\ast^\lambda - f_{\varphi}^\lambda \right\|_{\mathcal{L}_4(\Pi)},
\]

where we used (7.15) to bound \( \|\eta\|_{\psi_2} \). For all \( \lambda \in \Lambda(\delta, \Delta, R) \), this implies

\[
\left\| \eta(f_\ast^\lambda - f_{\varphi}^\lambda) \right\|_{\mathcal{L}(P)} \leq c_2 \left( \left\| f_{\varphi} - f_\ast \right\|_{\mathcal{L}_4(\Pi)} + \left\| \xi \right\|_{\psi_2} \right).
\]

Using (A.3), we will also estimate the envelope of the class \( \mathcal{F}(\delta, \Delta, R) \) as follows:

\[
\sup_{\lambda \in \Lambda(\delta, \Delta, R)} \left\| \eta(X, Y) (f_\ast^\lambda(X) - f_{\varphi}^\lambda(X)) \right\|_{\psi_1} \leq \left\| \eta(X, Y) \right\|_{\psi_1} \left\| \sup_{\lambda \in \Lambda(\delta, \Delta, R)} \left( f_\ast^\lambda(X) - f_{\varphi}^\lambda(X) \right) \right\|_{\psi_2}.
\]
Recall that $L$ is a subspace of the subgaussian space $\mathcal{L}$ with $\dim(L) = d$ and

$$
\rho = \sup_{t \in \mathcal{T}} \|P_L (X(t) - E X(t))\|_{L^2(\mathbb{P})}.
$$

Let $\zeta_1, \ldots, \zeta_d$ be an orthonormal basis of $L \subset L_2(\mathbb{P})$. For $u = \lambda - \overline{\lambda}$, the following decomposition holds:

$$
f_\lambda^0(X) - f_\lambda^0(X) = \langle u, X - E X \rangle = P_L (u, X - E X)
$$

$$+ \int_{\mathcal{T}} P_L (X - E X)(t) u(t) \mu(dt) + \int_{\mathcal{T} \setminus \mathcal{T}} P_L (X - E X)(t) u(t) \mu(dt).
$$

We have

$$
\sup_{\lambda \in A(\delta, \Delta, R)} \left\| P_L \langle \lambda - \overline{\lambda}, X - E X \rangle \right\|_{\psi_2} \leq \sup \left\{ \left| \sum_{k=1}^d \alpha_k \zeta_k \right| : \sum_{k=1}^d \alpha_k^2 \leq \delta^2 \right\}
$$

$$\leq \delta \sqrt{d} \left[ \frac{1}{d} \sum_{k=1}^d \zeta_k^2 \right]^{1/2} \| \psi_1 \| \leq \delta \sqrt{d} \sum_{k=1}^d \zeta_k^2 \| \psi_1 \|^{1/2}
$$

$$\leq \delta \sqrt{d} \max_{1 \leq k \leq d} \| \zeta_k \| \| \psi_1 \| \leq C \delta \sqrt{d}.
$$

We also easily get

$$
\left\| \sup_{\lambda \in A(\delta, \Delta, R)} \left( P_L (X - E X)(t) (\lambda - \overline{\lambda})(t) \mu(dt) \right) \right\|_{\psi_2}
$$

$$\leq (R + \| \overline{\lambda} \|) \left\| \sup_{t \in \mathcal{T}} P_L (X - E X)(t) \right\|_{\psi_2} \leq C(R + \| \overline{\lambda} \|) \gamma_2(\rho)
$$

and

$$
\left\| \sup_{\lambda \in A(\delta, \Delta, R)} \left( P_L (X - E X)(t) (\lambda - \overline{\lambda})(t) \mu(dt) \right) \right\|_{\psi_2} \leq \Delta \left\| \sup_{t \in \mathcal{T}} P_L (X - E X)(t) \right\|_{\psi_2} \leq C \Delta S(T).
$$

It implies that

$$
(7.17) \quad \left\| \sup_{\lambda \in A(\delta, \Delta, R)} |f_\lambda^0(X) - f_\lambda^0(X)| \right\|_{\psi_1} \leq C \left[ \delta \sqrt{d} + (R + \| \overline{\lambda} \|) \gamma_2(\rho) + \Delta S(T) \right].
$$

Thus,

$$
\left\| \sup_{\lambda \in A(\delta, \Delta, R)} |g(X,Y)(f_\lambda^0(X) - f_\lambda^0(X))| \right\|_{\psi_1}
$$

$$\leq C \left( \| f_{\overline{\lambda}^\top} - f_* \|_{L_2(\mathbb{P})} + \| \xi \|_{\psi_2} \right) \left[ \delta \sqrt{d} + (R + \| \overline{\lambda} \|) \gamma_2(\rho) + \Delta S(T) \right].
$$
It follows from Adamczak’s bound (A.7) and the second statement of Proposition A.1 that, with probability at least \(1 - e^{-s}\),

\[
\alpha_n(\delta, \Delta, R) \leq C \left[ \mathbb{E} \alpha_n(\delta, \Delta, R) + (\|f_{\mathbb{X}, \pi} - f\|_{L_2(\Pi)} + \|\xi\|_{\psi_2}) \delta \sqrt{n} \right. \\
+ \left. (\|f_{\mathbb{X}, \pi} - f\|_{L_2(\Pi)} + \|\xi\|_{\psi_2}) \left[ \delta \sqrt{d} + (R + \|\mathbb{X}\|_1) \gamma(\rho) + \Delta S(|\mathbb{Y}|) + s \log n \right] \right].
\]

Combining this with the bound of Lemma 7.2, taking the infimum of the right-hand side with respect to \(L \in \mathcal{L}'\) and recalling that, according to our assumptions, \(s \log n / \sqrt{n}\) is bounded by an absolute constant, we derive the following inequality:

\[
(7.18) \quad \alpha_n(\delta, \Delta, R) \leq \beta_n(\delta, \Delta, R; s) := C(\|f_{\mathbb{X}, \pi} - f\|_{L_2(\Pi)} \lor \|\xi\|_{\psi_2}) \left[ \delta \sqrt{\frac{2}{n}} \lor \nu_n(\delta, \Delta, R) \right] \lor C \nu_n^2(\delta, \Delta, R)
\]

that holds with probability at least \(1 - e^{-s}\).

We still need to make the last bound uniform in \(\delta \in [\delta_-, \delta_+]\), \(\Delta \in [\Delta_-, \Delta_+]\), \(R \in [R_-, R_+]\). To this end, define \(\delta_{j_1} := \delta_1 2^{-j_1}, \Delta_{j_2} := \Delta_1 2^{-j_2}\) and \(R_{j_3} := R_1 2^{-j_3}\) for \(j_1 = 0, 1, \ldots, J_1, j_2 = 0, 1, \ldots, J_2, j_3 = 0, 1, \ldots, J_3\). Using bound (7.18) for each \(\delta_{j_1}, \Delta_{j_2}, R_{j_3}\) with \(s\) replaced by \(\bar{s} := s + \log((J_1 + 1)(J_2 + 1)(J_3 + 1))\) and applying then the union bound, we get that with probability at least \(1 - e^{-s}\) \(\alpha_n(\delta_{j_1}, \Delta_{j_2}, R_{j_3}) \leq \beta_n(\delta_{j_1}, \Delta_{j_2}, R_{j_3}; \bar{s})\) for all \(j_k = 0, \ldots, J_k, k = 1, 2, 3\). By monotonicity of the functions \(\alpha_n, \beta_n\) in their variables this easily implies that with the same probability

\[
\alpha_n(\delta, \Delta, R) \leq C \left( \|f_{\mathbb{X}, \pi} - f\|_{L_2(\Pi)} \lor \|\xi\|_{\psi_2} \right) \left[ \delta \sqrt{\frac{2}{n}} \lor \nu(\delta, \Delta, R) \right] \lor C \nu^2(\delta, \Delta, R).
\]

for all \(\delta \in [\delta_-, \delta_+]\), \(\Delta \in [\Delta_-, \Delta_+]\), \(R \in [R_-, R_+]\) and for a large enough constant \(C > 0\). \(\Box\)

Bounding the last three terms in the right-hand side of (7.11) is easier. Since \(\eta(X, Y)\) is a subgaussian random variable (its mean is equal to zero and its \(\psi_2\)-norm is finite) and (7.15) holds, we have the following tail bound:

\[
(7.19) \quad |(P_n - P)\eta| = \left| \sum_{j=1}^{n} \eta(X_j, Y_j) \right| \leq C(\|f_{\mathbb{X}, \pi} - f\|_{L_2(\Pi)} \lor \|\xi\|_{\psi_2}) \sqrt{\frac{s}{n}}
\]

with probability at least \(1 - e^{-s}\) and with some constant \(C > 0\). Moreover, using the representation \(Y - EY = f_*(X) - Ef_*(X) + \xi\) and the assumption that \(f_*(X) - Ef_*(X)\) is bounded, we get

\[
\|Y - EY\|_{\psi_2} \leq \|f_*(X) - Ef_*(X)\|_{\psi_2} + \|\xi\|_{\psi_2}
\]

\[
\leq c \|f_*(X) - Ef_*(X)\|_{L_2(\Pi)} + \|\xi\|_{\psi_2}
\]

\[
= c \|f_* - Pf_*\|_{L_2(\Pi)} + \|\xi\|_{\psi_2}.
\]

J.E.P. – M., 2014, tome 1
Since $Y - \mathbb{E}Y$ is subgaussian, it is easy to deduce that

$$
(7.20) \quad |\overline{Y}_n - \mathbb{E}Y| = \left| \sum_{j=1}^{n-1} (Y_j - \mathbb{E}Y) \right| \leq C \left( \| f_\ast - \Pi f_\ast \|_{L^2(\Pi)} \lor \| \xi \|_{\psi_2} \right) \sqrt{\frac{s}{n}}
$$

with probability at least $1 - e^{-s}$ and with some constant $C > 0$. Therefore,

$$
(7.21) \quad |\overline{Y}_n - \mathbb{E}Y| \cdot |(P_n - P)\eta| \leq C \left( \| f_\ast - \Pi f_\ast \|_{L^2(\Pi)} \lor \| f_{\overline{X},\pi} - f_\ast \|_{L^2(\Pi)} \lor \| \xi \|_{\psi_2} \right) \sqrt{\frac{s}{n}}
$$

with probability at least $1 - 2e^{-s}$. Since $\langle \overline{X}, X_j - \mathbb{E}X_j \rangle$ are i.i.d. subgaussian random variables, their average $\langle \overline{X}, \overline{X}_n - \mathbb{E}X \rangle$ is also subgaussian. This easily yields the bound

$$
(7.22) \quad \left| \langle \overline{X}, \overline{X}_n - \mathbb{E}X \rangle \right| \leq C \left( \| f_\ast - \Pi f_\ast \|_{L^2(\Pi)} \lor \| f_{\overline{X},\pi} - f_\ast \|_{L^2(\Pi)} \lor \| \xi \|_{\psi_2} \right) \sqrt{\frac{s}{n}}
$$

that holds with probability at least $1 - e^{-s}$ and with some $C > 0$. Therefore, with probability at least $1 - 2e^{-s}$

$$
(7.23) \quad \left| \langle \overline{X}, \overline{X}_n - \mathbb{E}X \rangle \right| \cdot |(P_n - P)\eta| \leq C \left( \| f_\ast - \Pi f_\ast \|_{L^2(\Pi)} \lor \| f_{\overline{X},\pi} - f_\ast \|_{L^2(\Pi)} \lor \| \xi \|_{\psi_2} \right) \sqrt{\frac{s}{n}}
$$

The proof of the next lemma is a simplified version of the proofs of Lemmas 7.2, 7.3. Together with (7.19) it will be used to control the term

$$
|(P_n - P)\eta| \cdot \tau_n \left( \| f_\{\lambda\}^0 - f_\{\lambda\}^0 \|_{L^2(\Pi)}, \int_{\mathbb{T} \setminus \mathbb{T}^w} |\lambda| d\mu, \| \lambda \|_1 \right)
$$

in the right-hand side of (7.11).

**Lemma 7.4.** — There exists a constant $C > 0$ such that the following holds. Under the notations of Lemma 7.3, with probability at least $1 - e^{-s}$ and with

$$
\tau := s + \log \left( (J_1 + 1)(J_2 + 1)(J_3 + 1) \right)
$$

satisfying the condition $s \sqrt{\log n} \leq \sqrt{n}$,

$$
\tau_n(\delta, \Delta, R) = \sup \left\{ \left| (\Pi_n - \Pi)(f_\lambda^0 - f_\{\lambda\}^0) \right| : \lambda \in \Lambda(\delta, \Delta, R) \right\} \leq C \left[ \delta \sqrt{\frac{s}{n}} \lor \nu_n(\delta, \Delta, R) \right]
$$

uniformly for all $\delta \in [\delta_-, \delta_+]$, $\Delta \in [\Delta_-, \Delta_+]$, $R \in [R_-, R_+]$.

**Step 3. Bounds for $(\Pi - \Pi_n)(f_\lambda^0 - f_\{\lambda\}^0)^2$.** — We will need the following representation (that is a consequence of (7.10)):

$$
(7.24) \quad (\Pi - \Pi_n)(f_\lambda^0 - f_\{\lambda\}^0)^2 = (\Pi - \Pi_n)(f_\lambda^0 - f_\{\lambda\}^0)^2 + 2(\Pi - \Pi_n)(f_\lambda^0 - f_\{\lambda\}^0)(\overline{Y}_n - \mathbb{E}Y)
$$

$$
+ 2(\Pi - \Pi_n)(f_\lambda^0 - f_\{\lambda\}^0)(\overline{X} \cdot \mathbb{E}X - \overline{X}_n) + 2 \left[ (\Pi - \Pi_n)(f_\lambda^0 - f_\{\lambda\}^0)^2 \right]^{\frac{1}{2}}
$$

$$
=: (\Pi - \Pi_n)(f_\lambda^0 - f_\{\lambda\}^0)^2 + c_n(\lambda).
$$
Using bounds (7.20), (7.22) and Lemma 7.4, it yields that with probability at least $1 - 3e^{-s}$ for the same $\delta, \Delta, R$

\begin{equation}
(7.25) \quad \sup \left\{ |\zeta_n(\lambda)| : \lambda \in \Lambda(\delta, \Delta, R) \right\} \leq C \left[ \delta \sqrt{\frac{s}{n}} \vee \nu_n(\delta, \Delta, R) \right]^2 
\end{equation}

\[ \vee C \left( \|f_* - \Pi f_*\|_{L_2(\Pi)} \vee \|f_{\lambda, a} - f_*\|_{L_2(\Pi)} \vee \|\xi\|_{\psi_2} \right) \sqrt{\frac{s}{n}} \left[ \delta \sqrt{\frac{s}{n}} \vee \nu_n(\delta, \Delta, R) \right]. \]

Next, we have to estimate

\[ \psi_n(\delta, \Delta, R) := \sup_{\lambda \in \Lambda(\delta, \Delta, R)} \| (\Pi_n - \Pi)(f^0_\lambda - f^0_\Lambda) \|_{\psi_2}. \]

**Lemma 7.5.** There exists a constant $C > 0$ such that the following holds. Under the notations of Lemma 7.3, with probability at least $1 - e^{-s}$

\[ \psi_n(\delta, \Delta, R) \leq C \delta \left[ \delta \sqrt{\frac{s}{n}} \vee \nu_n(\delta, \Delta, R) \right] \vee C \nu_n^2(\delta, \Delta, R) \]

uniformly for all $\delta \in [\delta_-, \delta_+]$, $\Delta \in [\Delta_-, \Delta_+]$, $R \in [R_-, R_+]$.

**Proof.** The proof is based on the inequality due to S. Dirksen and W. Bednorz (see Theorem A.5 in the appendix). To this end, we need to estimate several quantities appearing in that bound. First, note that, since \{ $f(X) : f \in \mathcal{F}(\delta, \Delta, R)$ \} is a subset of a subgaussian space,

\[ \sup_{f \in \mathcal{F}(\delta, \Delta, R)} \|f\|_{\psi_2} \leq C \sup_{f \in \mathcal{F}(\delta, \Delta, R)} \|f\|_{L_2(\Pi)} \leq \delta \delta. \]

Together with the bound (7.14) on $\gamma_2(\mathcal{F}; \psi_2)$, Theorem A.5 implies that with probability $\geq 1 - e^{-s}$,

\[ \psi_n(\delta, \Delta, R) \leq C \delta \left[ \delta \sqrt{\frac{d}{n}} \vee (R \vee \|X\|_1) \frac{\gamma_2(\rho)}{\sqrt{m}} \vee \Delta \frac{S(T)}{\sqrt{n}} \right] \]

\[ \vee C \left[ \delta \sqrt{\frac{d}{n}} \vee (R \vee \|X\|_1) \frac{\gamma_2(\rho)}{\sqrt{m}} \vee \Delta \frac{S(T)}{\sqrt{n}} \right]^2 \vee C \delta^2 \left[ \sqrt{\frac{s}{n}} \vee \sqrt{\frac{s}{n}} \right]. \]

It remains to combine the discretization argument as in the proof of Lemma 7.3 with an application of the union bound to get an estimate for $\psi_n(\delta, \Delta, R)$ that holds uniformly in $\delta, \Delta, R$ with a high probability. As a result, we get that

\[ \psi_n(\delta, \Delta, R) \leq C \delta \left[ \delta \sqrt{\frac{s}{n}} \vee \nu_n(\delta, \Delta, R) \right] \vee C \nu_n^2(\delta, \Delta, R) \]

with probability at least $1 - e^{-s}$ for all $\delta \in [\delta_-, \delta_+]$, $\Delta \in [\Delta_-, \Delta_+]$, $R \in [R_-, R_+]$ uniformly, and for a large enough constant $C > 0$. \(\square\)

\(J.E.P. - M., 2014, \text{tome 1}\)
Step 4. Upper bound on $\|\hat{\lambda}\|_1$.

Lemma 7.6. — There exist constants $C, D > 0$ such that the following holds. For all $s \geq 1$ and $\varepsilon$ satisfying the assumptions $s \log n \leq \sqrt{n}$ and $\varepsilon \geq D\|\xi\|_{\psi_2} S(T)\sqrt{s/n}$, with probability at least $1 - 5e^{-s}$,

$$\|\hat{\lambda}\|_1 \leq C \left( \frac{q(\varepsilon)}{\varepsilon} + \frac{\sigma^2 s}{n\varepsilon} \right).$$

Proof. — By the definition of $\hat{\lambda}$ for all $\lambda \in \mathbb{D}, a \in \mathbb{R}$

$$P_n(\ell \cdot f_{\hat{\lambda}, a}) + \varepsilon \|\hat{\lambda}\|_1 \leq P_n(\ell \cdot f_{\lambda, a}) + \varepsilon \|\lambda\|_1.$$  

We will take $a = a(\lambda) = \mathbb{E} Y - \langle \lambda, \mathbb{E} X \rangle$ everywhere below. Let $\xi(x, y) = y - f_*(x)$ (then, $\xi_j = \xi(X_j, Y_j)$). Since

$$\ell \cdot f_{\hat{\lambda}, a} - \ell \cdot f_{\lambda, a} = (f_{\hat{\lambda}, a} + f_{\lambda, a} - 2f_*(x))(f_{\hat{\lambda}, a} - f_{\lambda, a}),$$

it is easy to conclude that

$$P_n(\ell \cdot f_{\hat{\lambda}, a}) - P_n(\ell \cdot f_{\lambda, a}) = \|f_{\hat{\lambda}, a} - f_*\|_{L_2(\Pi_n)}^2 - \|f_{\lambda, a} - f_*\|_{L_2(\Pi_n)}^2 - 2P_n\xi(f_{\hat{\lambda}, a} - f_{\lambda, a}).$$

Thus, (7.26) implies that

$$\|f_{\hat{\lambda}, a} - f_*\|_{L_2(\Pi_n)}^2 + \varepsilon \|\hat{\lambda}\|_1$$

$$\leq \|f_{\lambda, a} - f_*\|_{L_2(\Pi)}^2 + (\Pi_n - \Pi)(f_{\lambda, a} - f_*)^2 + 2P_n\xi(f_{\hat{\lambda}, a} - f_{\lambda, a}) + \varepsilon \|\lambda\|_1.$$  

Using Bernstein’s inequality for the random variable with finite $\|\cdot\|_{\psi_1}$-norm (see [26], section A.2) we get that with probability at least $1 - e^{-s}$, for $s \leq n$

$$|(\Pi_n - \Pi)(f_{\lambda, a} - f_*)^2| \leq C_1 \|f_{\lambda, a} - f_*\|_{L_2(\Pi)}^2 \left[ \frac{s}{n} \sqrt{\frac{s}{n}} \right]$$

$$\leq C_1 \|f_{\lambda, a} - f_*\|_{L_2(\Pi)}^2 \sqrt{\frac{s}{n}},$$

where we also used the fact that

$$\|f_{\lambda, a} - f_*\|_{\psi_1} = \|f_{\lambda, a} - f_*\|_{\psi_2} \leq \varepsilon \|f_{\lambda, a} - f_*\|_{L_2(\Pi)}.$$  

Next, we apply representation (7.10) to term $f_{\hat{\lambda}, a} - f_{\lambda, a}$ in $P_n\xi(f_{\hat{\lambda}, a} - f_{\lambda, a})$ to get the following bound:

$$\|P_n\xi(f_{\hat{\lambda}, a} - f_{\lambda, a})| \leq \|\hat{\lambda} - \lambda\|_1 \left[ \frac{1}{n} \sum_{j=1}^n \xi_j(X_j - \mathbb{E} X) \right]$$

$$+ \left[ \frac{1}{n} \sum_{j=1}^n \xi_j \right] \left| \mathbb{E} n - \mathbb{E} Y + \langle \hat{\lambda}, \mathbb{E} X - \mathbb{E} X \rangle \right|.$$  

To bound the first term in the right-hand side of (7.29), we use a general multiplier inequality (see [41], Lemma 2.9.1):

$$\mathbb{E} \left| \frac{1}{\sqrt{n}} \sum_{j=1}^n \xi_j(X_j - \mathbb{E} X) \right|_{\infty} \leq 2\sqrt{\mathbb{E} \|\xi\|_{2,1}} \max_{1 \leq i \leq n} \mathbb{E} \left| \frac{1}{\sqrt{k}} \sum_{j=1}^k \varepsilon_j(X_j - \mathbb{E} X) \right|_{\infty}.$$  

J.É.P — M. 2004, tome 1
where \( \| \xi \|_{2,1} := \int_0^\infty \sqrt{P(\xi \geq u)} \, du \). Note that the process

\[
t \mapsto \frac{1}{\sqrt{k}} \sum_{j=1}^k \varepsilon_j (X_j(t) - \mathbb{E} X(t))
\]

is subgaussian for every \( k \) with respect to the distance \( d_X \). Therefore,

\[
\mathbb{E} \left\| \frac{1}{\sqrt{k}} \sum_{j=1}^k \varepsilon_j (X_j - \mathbb{E} X) \right\|_\infty \leq C_1 S(T),
\]

which yields

\[
(7.30) \quad \mathbb{E} \left\| \frac{1}{n} \sum_{j=1}^n \xi_j (X_j - \mathbb{E} X) \right\|_\infty \leq C_2 \| \xi \|_{\psi_2} \frac{S(T)}{\sqrt{n}},
\]

where we also used the bound \( \| \xi \|_{2,1} \leq c \| \xi \|_{\psi_2} \).

Adamczak’s inequality (A.7) implies that with probability \( \geq 1 - e^{-s} \)

\[
(7.31) \quad \left\| \frac{1}{n} \sum_{j=1}^n \xi_j (X_j - \mathbb{E} X) \right\|_\infty \leq C \left\| \xi \right\|_{\psi_2} \frac{S(T)}{\sqrt{n}} + \sigma_\xi \sup_{t \in T} \sqrt{\mathbb{V} \mathrm{a}r(X(t))} \frac{s}{n} + \| \xi \|_{\psi_2} S(T) \frac{s \log n}{n}.
\]

where we also used the bound \( \sup_{t \in T} \sqrt{\mathbb{V} \mathrm{a}r(X(t))} \leq \mathbb{E}^{1/2} \sup_{t \in T} |X(t) - \mathbb{E} X(t)|^2 \leq C S(T) \).

To estimate the second term in (7.29), we use inequality (7.20) and also the following tail bounds: with probability at least \( 1 - e^{-s} \),

\[
(7.33) \quad \left\| \frac{1}{n} \sum_{j=1}^n \xi_j \right\| \leq C \| \xi \|_{\psi_2} \sqrt{\frac{s}{n}}
\]

and, with the same probability,

\[
(7.34) \quad \| X_n - \mathbb{E} X \|_\infty \leq C S(T) \sqrt{\frac{s}{n}}.
\]

Together with (7.20), these bounds imply that, for some \( C > 0 \), with probability at least \( 1 - 3e^{-s} \),

\[
(7.35) \quad \left| \frac{1}{n} \sum_{j=1}^n \xi_j \right| \| Y_n - \mathbb{E} Y + \langle \hat{\lambda}, \mathbb{E} X - X_n \rangle \|
\]

\[
\leq C \| \xi \|_{\psi_2} \left[ S(T) \frac{s}{n} \| \hat{\lambda} \|_1 + \frac{\| f_* - \Pi f_* \|_{L^2(\Pi)} \vee \| \xi \|_{\psi_2} s}{n} \right].
\]
It follows from bounds (7.27), (7.28), (7.29), (7.31) and (7.35) that with probability at least $1 - 5e^{-s}$

\[
\varepsilon\|\hat{\lambda}\|_1 \leq \|f_{\lambda,a} - f_s\|_{L_2(\Pi)}^2 + C_1\|f_{\lambda,a} - f_s\|_{L_2(\Pi)} \sqrt{\frac{s}{n}} + \varepsilon\|\lambda\|_1
\]

\[
+ C'\|\xi\|_{\psi_2} S(T) \sqrt{\frac{s}{n}}\|\hat{\lambda} - \lambda\|_1 + C\|\xi\|_{\psi_2} S(T) \frac{s}{n}\|\hat{\lambda}\|_1
\]

\[
+ C\left(\frac{\|f_s - \Pi f_s\|_{L_2(\Pi)}^2 \lor \|\xi\|_{\psi_2}^2 s}{n}\right).
\]

If constant $D$ in the assumption on $\varepsilon$ is large enough and $s \leq n$, it implies that with some $C > 0$

\[
\frac{\varepsilon}{2}\|\hat{\lambda}\|_1 \leq C\|f_{\lambda,a} - f_s\|_{L_2(\Pi)}^2 + 2\varepsilon\|\lambda\|_1 + C\left(\frac{\|f_s - \Pi f_s\|_{L_2(\Pi)}^2 \lor \|\xi\|_{\psi_2}^2 s}{n}\right),
\]

and the result immediately follows. □

**Step 5. Putting all the bounds together.** — We have all the necessary estimates to complete the proof. Let $E$ denote the event on which the bounds of Lemma 7.3, Lemma 7.4, Lemma 7.5 and also bounds (7.19), (7.20), (7.22), (7.28), (7.31), (7.33) and (7.34) hold. The probability of this event is at least $1 - 10e^{-s}$. In what follows, we assume that event $E$ occurs. Note that in this case the bound of Lemma 7.6 also holds. Denote

\[
\hat{\delta} := \|f^0_\lambda - f^0_\lambda\|_{L_2(\Pi)}, \quad \hat{\Delta} := \int_{\mathcal{T}\setminus\tau_w} |\hat{\lambda}| d\mu, \quad \hat{R} := \|\hat{\lambda}\|_1.
\]

Suppose that

\[(7.36) \quad \hat{\delta} \in [\delta_-, \delta_+], \quad \hat{\Delta} \in [\Delta_-, \Delta_+], \quad \hat{R} \in [R_-, R_+].\]

It follows from bound (7.11), Lemma 7.3 and bounds (7.21) – (7.23) that

\[(7.37) \quad \frac{1}{C}(P_n - P) \left[ \eta \left(f_{\lambda,a} - f_{\lambda,\varphi}\right) \right]
\]

\[
\leq \left(\|f_{\lambda,\varphi} - f_s\|_{L_2(\Pi)} \lor \|\xi\|_{\psi_2}\right) \left[\hat{\delta}\sqrt{\frac{s}{n}} \lor \nu_n(\hat{\delta}, \hat{\Delta}, \hat{R}) \right]
\]

\[
\lor \nu^2_n(\hat{\delta}, \hat{\Delta}, \hat{R}) \lor \left(\|f_s - \Pi f_s\|_{L_2(\Pi)}^2 \lor \|f_{\lambda,\varphi} - f_s\|_{L_2(\Pi)} \lor \|\xi\|_{\psi_2}^2 \right)^{\frac{s}{n}}
\]

\[
\lor \left(\|f_{\lambda,\varphi} - f_s\|_{L_2(\Pi)} \lor \|\xi\|_{\psi_2}\right) \left[\hat{\delta}\sqrt{\frac{s}{n}} \lor \nu_n(\hat{\delta}, \hat{\Delta}, \hat{R}) \right]
\]

for some absolute constant $C > 0$. Similarly, Lemma 7.5 and bound (7.25) imply that

\[(7.38) \quad \frac{1}{C}(\Pi - \Pi_n)(f_{\lambda,a} - f_{\lambda,\varphi})^2 \leq \hat{\delta}\left[\frac{\hat{\delta}}{\sqrt{s}} \lor \nu_n(\hat{\delta}, \hat{\Delta}, \hat{R}) \right] \lor \lambda^2 \left[\frac{\hat{\delta}}{\sqrt{s}} \lor \nu_n(\hat{\delta}, \hat{\Delta}, \hat{R}) \right]
\]

\[
\lor \left(\|f_s - \Pi f_s\|_{L_2(\Pi)} \lor \|f_{\lambda,\varphi} - f_s\|_{L_2(\Pi)} \lor \|\xi\|_{\psi_2}\right) \left[\hat{\delta}\sqrt{\frac{s}{n}} \lor \nu_n(\hat{\delta}, \hat{\Delta}, \hat{R}) \right]
\]

\[
\lor \left[\frac{\hat{\delta}}{\sqrt{s}} \lor \nu_n(\hat{\delta}, \hat{\Delta}, \hat{R}) \right]^2.
\]

---

J. E. P. — M., 2014, tome 1
Whenever it is more convenient, we can replace the maximum
\[ (7.40) \]
and inequality (7.39) easily yields
the maximum, etc. With such simple transformations, it is easy to get the following
use elementary inequalities such as
\[ \text{The last two inequalities will be replaced by simplified upper bounds. To this end, we} \]
\[ (7.39) \]
\[ C(\|f_{\hat{\xi}, \pi} - f_*\|_{L_2(\Omega)} \vee \|\xi\|_2) \delta \sqrt{\frac{8}{n}} \leq \frac{2C^2}{2} \left( \|f_{\hat{\xi}, \pi} - f_*\|^2_{L_2(\Omega)} \vee \|\xi\|^2_2 \right) + \frac{1}{8} \delta^2. \]
Also recall that by (7.4), (3.1) and the assumption that \( \xi \in \mathcal{Z} \),
\[ \|f_* - \Pi f_*\|_{L_2(\Omega)} \vee \|f_{\hat{\xi}, \pi} - f_*\|_{L_2(\Omega)} \vee \|\xi\|_2 \leq \sigma_Y. \]
Whenever it is more convenient, we can replace the maximum \( \vee \) by the sum, or
vice versa (with a proper change of constant \( C \)), we can drop repetitive terms in
the maximum, etc. With such simple transformations, it is easy to get the following
bound (with some constant \( C > 0 \) and under the assumption that \( \pi \leq n \)):
\[ (7.39) \]
\[ (P_n - P)\eta(f_{\hat{\xi}, \hat{\alpha}} - f_{\hat{\xi}, \pi}) + (\Pi - \Pi_n)(f_{\hat{\xi}, \hat{\alpha}} - f_{\hat{\xi}, \pi})^2 \]
\[ \leq \frac{1}{8} \delta^2 + C \delta^2 \sqrt{\frac{8}{n}} + C \sigma_Y \nu_n(\hat{\delta}, \hat{\Delta}, \hat{R}) + C \nu_n^2(\hat{\delta}, \hat{\Delta}, \hat{R}) + C \frac{\sigma^2 \pi}{n}. \]
Note that
\[ \nu_n(\hat{\delta}, \hat{\Delta}, \hat{R}) = \inf_{L \subseteq \mathcal{Z}} \left[ \delta \sqrt{\frac{\dim(L)}{n}} \right] \right) \frac{\gamma_2(\rho(L))}{\sqrt{n}} \sqrt{\Delta} \frac{S(T)}{\sqrt{n}} \right) \leq \left( \hat{R} \vee \|\hat{\xi}\|_1 \right) \frac{S(T)}{\sqrt{n}}, \]
where we used the bounds \( \hat{\Delta} \leq \hat{R} \), \( \gamma_2(\rho) \leq \frac{S(T)}{\sqrt{n}} \) and computed the expression in the
right-hand side of the definition of \( \nu_n \) for a trivial subspace of zero dimension. Using
Lemma 7.6, we get the following bound:
\[ \hat{R} \vee \|\hat{\xi}\|_1 \leq c \left( \frac{g(\epsilon)}{\epsilon} \sqrt{\frac{\sigma^2 \pi}{n}} \right) \frac{S(T)}{\sqrt{n}}, \]
which holds with probability at least \( 1 - e^{-\delta} \). Therefore,
\[ \nu_n^2(\hat{\delta}, \hat{\Delta}, \hat{R}) \leq c \left( \frac{g(\epsilon)}{\epsilon} \sqrt{\frac{\sigma^2 \pi}{n}} \right) \frac{S(T)}{\sqrt{n}} \nu_n(\hat{\delta}, \hat{\Delta}, \hat{R}) + \|\hat{\xi}\|_1 \frac{S(T)}{\sqrt{n}} \nu_n(\hat{\delta}, \hat{\Delta}, \hat{R}) \]
\[ \leq c \left( \frac{g(\epsilon)}{\epsilon} \sqrt{\frac{\sigma^2 \pi}{n}} \right) \frac{S(T)}{\sqrt{n}} \nu_n(\hat{\delta}, \hat{\Delta}, \hat{R}) + \frac{1}{2} \frac{\|\hat{\xi}\|^2_1 S^2(T)}{n} + \frac{1}{2} \nu_n^2(\hat{\delta}, \hat{\Delta}, \hat{R}), \]
and inequality (7.39) easily yields
\[ (7.40) \]
\[ (P_n - P)\eta(f_{\hat{\xi}, \hat{\alpha}} - f_{\hat{\xi}, \pi}) + (\Pi - \Pi_n)(f_{\hat{\xi}, \hat{\alpha}} - f_{\hat{\xi}, \pi})^2 \leq \frac{1}{8} \delta^2 + C \delta^2 \sqrt{\frac{8}{n}} \]
\[ + C \sigma_Y \nu_n(\hat{\delta}, \hat{\Delta}, \hat{R}) + C \left( \frac{g(\epsilon)}{\epsilon} \sqrt{\frac{\sigma^2 \pi}{n}} \right) \frac{S(T)}{\sqrt{n}} \nu_n(\hat{\delta}, \hat{\Delta}, \hat{R}) \]
\[ + C \frac{\|\hat{\xi}\|^2_1 S^2(T)}{n} + C \frac{\sigma^2 \pi}{n}. \]

**Remark 7.1.** — Note that under an additional assumption that
\[ \mathbb{D} \subset \left\{ \lambda \in L_1(\mu) : \|\lambda\|_1 \leq \frac{C \sigma_Y \sqrt{n}}{S(T)} \right\} \]
(in particular, \(\|\overline{X}\|_1 \leq C\sigma_Y\sqrt{n}/S(\mathbb{T})\)), we have
\[
\nu_n^2(\hat{\delta}, \hat{\Delta}, \hat{R}) \leq c \left( \frac{q(\varepsilon)}{\varepsilon} \sqrt{\frac{\tilde{\sigma}^2 S}{n^2}} \right) \frac{S(\mathbb{T})}{\sqrt{n}} \nu_n(\delta, \Delta, R) + \|\overline{X}\|_1 \frac{S(\mathbb{T})}{\sqrt{n}} \nu_n(\delta, \Delta, R)
\]
\[
\leq c \left( \frac{q(\varepsilon)}{\varepsilon} \sqrt{\frac{\tilde{\sigma}^2 S}{n^2}} \right) \frac{S(\mathbb{T})}{\sqrt{n}} \nu_n(\delta, \Delta, R) + C\sigma_Y \nu_n(\delta, \Delta, R),
\]
so that the term \(\|\overline{X}\|_2^2 S^2(\mathbb{T})/n\) disappears from (7.40). In this case, the remainder of the proof yields Theorem 3.3.

Under the assumption (3.5) on \(\varepsilon\) and the inequality \(s \leq cn\) (which easily follows from the the main conditions of the theorem), we have
\[
\frac{s\sigma_Y}{n\varepsilon} \frac{S(\mathbb{T})}{\sqrt{n}} \leq c_1
\]
with some constant \(c_1 > 0\). Also, condition (3.5) and the inequality
\[
q(\varepsilon) \leq \|f_* - \Pi f_*\|^2_{L^2(\Pi)} \leq \sigma_Y^2
\]
imply that \(\frac{q(\varepsilon)}{\varepsilon} \leq c\sigma_Y\). Hence, with some constant \(C > 0\) and for any subspace \(L \subset \mathcal{L}_X\) with \(\dim(L) = d\) and \(\rho(L) = \rho\),
\[
(7.41) \quad (P_n - P)\eta(f_{\hat{\lambda}, \hat{\alpha}} - f_{\overline{\lambda}, \overline{\alpha}}) + (\Pi - \Pi_n)(f_{\hat{\lambda}, \hat{\alpha}} - f_{\overline{\lambda}, \overline{\alpha}})^2
\]
\[
\leq \frac{1}{8}\tilde{\delta}^2 + C\tilde{\delta}^2 \sqrt{\frac{\pi}{n}} + C\sigma_Y \left[ \tilde{\delta} \sqrt{\frac{d}{n}} \sqrt{(\hat{R} \vee \|\overline{X}\|_1)} \sqrt{\frac{\tilde{\sigma}^2}{n}} \sqrt{\frac{S(\mathbb{T})}{\sqrt{n}}} \right]
\]
\[
+ C \|\overline{X}\|^2_{S^2(\mathbb{T})} + C \frac{\sigma_Y^2}{n}.  
\]

We will now substitute (7.41) in the right-hand side of bound (7.8). Recall that \(\mathbb{T}_\mathcal{M} = \{t : \overline{w}(t) \geq 1/2\}\). Since, by monotonicity of subdifferentials, we have \((\hat{w}(t) - w(t))(\hat{\lambda}(t) - \lambda(t)) \geq 0\) for all \(t \in \mathbb{T}\), and \(\overline{w}, \hat{w}\) take their values in \([-1, 1]\) by definition, we also have that
\[
(7.42) \quad \langle \hat{w} - \overline{w}, \hat{\lambda} - \lambda \rangle \geq \frac{1}{2} \int_{\mathbb{T} \setminus \mathbb{T}_\mathcal{M}} |\hat{\lambda}| d\mu.
\]
Taking this into account, we get
\[
(7.43) \quad \|f_{\hat{\lambda}, \hat{\alpha}} - f_*\|_{L^2(\Pi)}^2 + \|f_{\hat{\lambda}, \hat{\alpha}} - f_{\overline{\lambda}, \overline{\alpha}}\|_{L^2(\Pi)}^2 + \frac{\varepsilon}{2} \langle \hat{w} - \overline{w}, \hat{\lambda} - \lambda \rangle + \frac{\varepsilon}{4} \int_{\mathbb{T} \setminus \mathbb{T}_\mathcal{M}} |\hat{\lambda}| d\mu
\]
\[
\leq \|f_{\hat{\lambda}, \hat{\alpha}} - f_*\|_{L^2(\Pi)}^2 + \varepsilon\langle \overline{w}, \overline{\lambda} - \lambda \rangle + \frac{1}{8}\tilde{\delta}^2 + C\tilde{\delta}^2 \sqrt{\frac{\pi}{n}}
\]
\[
+ C\sigma_Y \left[ \tilde{\delta} \sqrt{\frac{d}{n}} \sqrt{(\hat{R} \vee \|\overline{X}\|_1)} \sqrt{\frac{\tilde{\sigma}^2}{n}} \sqrt{\frac{S(\mathbb{T})}{\sqrt{n}}} \right]
\]
\[
+ C \|\overline{X}\|^2_{S^2(\mathbb{T})} + C \frac{\sigma_Y^2}{n}.
\]
Note also that
\[ \|\hat{\lambda}\| \leq \|\lambda\| + \langle \bar{w}, \hat{\lambda} - \lambda \rangle + \langle \hat{\omega} - \bar{w}, \hat{\lambda} - \lambda \rangle, \]
which will be used to control \( R \|\lambda\| = \|\hat{\lambda}\| \vee \|\lambda\| \). Then, bound (7.43) implies the following (with a different value of \( C \)):

\[
\|f_{\hat{\lambda}, \hat{a}} - f_*\|^2_{L_2(\Omega)} + \|f_{\hat{\lambda}, \hat{a}} - f_{\hat{\lambda}, \pi}\|^2_{L_2(\Omega)} + \frac{\varepsilon}{4} \langle \hat{\omega} - \bar{w}, \hat{\lambda} - \lambda \rangle + \frac{\varepsilon}{4} \hat{\lambda} \\
\leq \|f_{\lambda, \pi} - f_*\|^2_{L_2(\Omega)} + \frac{9}{8} \varepsilon \left( \|\bar{w}, \lambda - \hat{\lambda} \| \vee 0 \right) + \frac{1}{4} \hat{\Delta}^2 + C \varepsilon \frac{\Delta S(\Omega)}{\sqrt{n}} \\
+ C \varepsilon \left( \|\lambda\| + \|\lambda\| + \|\lambda\| \right) + C \frac{\varepsilon \Delta S(\Omega)}{n} + C \frac{\varepsilon \Delta S}{n}.
\]

If constant \( D \) in the condition on \( \varepsilon \) is large enough, we have
\[ C \varepsilon \gamma_2(\rho) \frac{S(\Omega)}{\sqrt{n}} \leq C \varepsilon \gamma_2(\rho) \frac{S(\Omega)}{\sqrt{n}} \leq \varepsilon / 8, \]
which implies

\[
\|f_{\hat{\lambda}, \hat{a}} - f_*\|^2_{L_2(\Omega)} + \|f_{\hat{\lambda}, \hat{a}} - f_{\hat{\lambda}, \pi}\|^2_{L_2(\Omega)} + \frac{\varepsilon}{4} \langle \hat{\omega} - \bar{w}, \hat{\lambda} - \lambda \rangle + \frac{\varepsilon}{8} \hat{\lambda} \\
\leq \|f_{\lambda, \pi} - f_*\|^2_{L_2(\Omega)} + \frac{9}{8} \varepsilon \left( \|\bar{w}, \lambda - \hat{\lambda} \| \vee 0 \right) + \frac{1}{4} \hat{\Delta}^2 + C \varepsilon \frac{\Delta S(\Omega)}{\sqrt{n}} \\
+ C \varepsilon \left( \|\lambda\| + \|\lambda\| + \|\lambda\| \right) + C \frac{\varepsilon \Delta S(\Omega)}{n} + C \frac{\varepsilon \Delta S}{n}.
\]

Finally, note that \( \hat{\delta} = \|f^0_{\hat{\lambda}} - f^0_{\lambda}\|^2_{L_2(\Omega)} \leq \|f_{\hat{\lambda}, \hat{a}} - f_{\hat{\lambda}, \pi}\|^2_{L_2(\Omega)} \). Because of this, under the assumption that \( C, \pi \) and \( n \) are such that \( C \frac{\Delta}{\sqrt{n}} \leq 1/4 \), we get from (7.45)

\[
\|f_{\hat{\lambda}, \hat{a}} - f_*\|^2_{L_2(\Omega)} + \frac{1}{4} \|f_{\hat{\lambda}, \hat{a}} - f_{\hat{\lambda}, \pi}\|^2_{L_2(\Omega)} + \frac{\varepsilon}{4} \langle \hat{\omega} - \bar{w}, \hat{\lambda} - \lambda \rangle + \frac{\varepsilon}{8} \hat{\lambda} \\
\leq \|f_{\lambda, \pi} - f_*\|^2_{L_2(\Omega)} + \frac{9}{8} \varepsilon \left( \|\bar{w}, \lambda - \hat{\lambda} \| \vee 0 \right) + C \varepsilon \frac{\Delta S(\Omega)}{\sqrt{n}} \\
+ C \varepsilon \left( \|\lambda\| + \|\lambda\| + \|\lambda\| \right) + C \frac{\varepsilon \Delta S(\Omega)}{n} + C \frac{\varepsilon \Delta S}{n}.
\]

First, assume that

\[
\frac{7}{8} \varepsilon \left( \|\bar{w}, \lambda - \hat{\lambda} \| \vee 0 \right) \geq C \varepsilon \frac{\Delta S(\Omega)}{\sqrt{n}} + C \varepsilon \left( \|\lambda\| + \|\lambda\| + \|\lambda\| \right) + C \frac{\varepsilon \Delta S(\Omega)}{n} + C \frac{\varepsilon \Delta S}{n}.
\]
In this case, bound (7.46) implies that

\[(7.48) \quad \|f_{\hat{\lambda},\alpha} - f_\alpha\|_{L^2(\Pi)}^2 + \frac{1}{2} \|f_{\hat{\lambda},\alpha} - f_{\hat{\lambda}}\|_{L^2(\Pi)}^2 + \frac{\epsilon}{8} \int_{\mathcal{T} \cap \mathcal{T}_\Pi} |\hat{\lambda}| d\mu \leq \|f_{\hat{\lambda},\pi} - f_\alpha\|_{L^2(\Pi)}^2 + 2\epsilon \langle \varpi, \lambda - \hat{\lambda} \rangle.\]

If \(\|f_{\hat{\lambda},\alpha} - f_\alpha\|_{L^2(\Pi)} \leq \|f_{\hat{\lambda},\pi} - f_\alpha\|_{L^2(\Pi)}\), the inequality of the theorem trivially holds. Otherwise, (7.48) implies that

\[\int_{\mathcal{T} \cap \mathcal{T}_\Pi} |\hat{\lambda} - \lambda| d\mu \leq 16 \langle \varpi, \lambda - \hat{\lambda} \rangle,\]

which means that \(\lambda - \hat{\lambda} \in C_{\varpi}^{(16)}\) and

\[\langle \varpi, \lambda - \hat{\lambda} \rangle \leq a(\varpi) \|f_\alpha - f_{\hat{\lambda},\pi}\|_{L^2(\Pi)} \leq a(\varpi) \|f_{\hat{\lambda},\alpha} - f_{\hat{\lambda}}\|_{L^2(\Pi)}\]

by the definition of \(a(\cdot) = a^{(16)}(\cdot)\). Therefore, we have

\[(7.49) \quad \|f_{\hat{\lambda},\alpha} - f_\alpha\|_{L^2(\Pi)}^2 + \frac{1}{2} \|f_{\hat{\lambda},\alpha} - f_{\hat{\lambda}}\|_{L^2(\Pi)}^2 + \frac{\epsilon}{8} \int_{\mathcal{T} \cap \mathcal{T}_\Pi} |\hat{\lambda}| d\mu \leq \|f_{\hat{\lambda},\pi} - f_\alpha\|_{L^2(\Pi)}^2 + 2\epsilon a(\varpi) |f_{\hat{\lambda},\alpha} - f_{\hat{\lambda}}|_{L^2(\Pi)} \leq \|f_{\hat{\lambda},\pi} - f_\alpha\|_{L^2(\Pi)}^2 + 2a(\varpi)^2 \epsilon^2 + \frac{1}{2} \|f_{\hat{\lambda},\alpha} - f_{\hat{\lambda}}\|_{L^2(\Pi)}^2 + 2\epsilon \langle \varpi, \lambda - \hat{\lambda} \rangle,\]

which again implies the bound of the theorem.

If condition (7.47) does not hold, then bound (7.46) implies that with some constant \(C > 0\)

\[(7.50) \quad \|f_{\hat{\lambda},\alpha} - f_\alpha\|_{L^2(\Pi)}^2 + \frac{\epsilon}{8} \int_{\mathcal{T} \cap \mathcal{T}_\Pi} |\hat{\lambda}| d\mu \leq \|f_{\hat{\lambda},\pi} - f_\alpha\|_{L^2(\Pi)}^2 + C \frac{\sigma_\gamma^2 d}{n} + C \sigma_Y \|\lambda\|_1 \sqrt{n} + \frac{C \|\varpi\|_2^2 S(\tau)}{n} + C \frac{\sigma_\gamma^2}{n},\]

which gives the bound of the theorem in this case. To complete the proof, it remains to choose the values of quantities \(\delta_-, \delta_+, \Delta_-, \Delta_+\) and \(R_-, R_+\) and to explain how to establish the bound of the theorem in the case when conditions (7.36) do not hold.

We will choose the values

\[\delta_+ := C_1 \sigma_Y \sqrt{n}, \quad \delta_- := C_1 \sigma_Y \sqrt{n},\]

\[R_+ = \Delta_+ = \frac{C_1 \sigma_Y \sqrt{n}}{S(\tau)}, \quad R_- = \Delta_- = \frac{C_1 \sigma_Y }{S(\tau) \sqrt{n}},\]

where \(C_1\) is a large enough constant. Recall that \(\pi = s + \log((J_1 + 1)(J_2 + 1)(J_3 + 1))\) and, for our choice of \(\delta_-, \delta_+, \Delta_-, \Delta_+, R_-, R_+\) we have \(J_1 = J_2 = J_3 = \lfloor \log_2 n \rfloor + 1\). Therefore, \(\pi = s + 3 \log(\lfloor \log_2 n \rfloor + 2)\). Since \(q(\epsilon) \leq \|f_\alpha - \Pi f_\alpha\|_{L^2(\Pi)}^2\), it easily follows from Lemma 7.6 that

\[\|\hat{\lambda}\|_1 \leq C \left[ \frac{q(\epsilon)}{\epsilon} + \frac{\sigma_\gamma^2 s}{n \epsilon} \right] \leq 2C_2 \frac{\sigma_\gamma^2}{\epsilon} \leq \frac{C_4 \sigma_Y }{S(\tau) \sqrt{n}} \leq R_+,\]
provided that constant $C_1$ is large enough. It is also easy to see from (7.5) that $\|\lambda\|_1 \leq R_+$. Thus, $\hat{R} \vee \|\lambda\|_1 \leq R_+$, and also $\hat{\Delta} \leq \hat{R} \leq R_+ = \Delta_+$. In addition,

$$\hat{\delta} = \|f_\lambda^0 - f_\lambda^0\|_{L_2(\Pi)} = E^{1/2}(\lambda - \lambda, X - EX)^2 \leq \|\lambda - \lambda\|_1 \sup_{t \in T} \sqrt{\text{Var}(X(t))}$$

$$\leq C_2(\hat{R} \vee \|\lambda\|_1)S(T) \leq C_2 \frac{\sigma \sqrt{\epsilon}}{S(T)} \sqrt{nS(T)} \leq \delta_+,$$

again, provided that constant $C_1$ is large enough. Here, we also used the bound (7.32) to estimate $\sup_{t \in T} \sqrt{\text{Var}(X(t))}$.

Thus, conditions $\delta \leq \delta_+, \hat{\Delta} \leq \Delta_+, \hat{R} \leq R_+$ hold on the event $E$. If some of the conditions $\hat{\delta} \geq \delta_+, \hat{\Delta} \geq \Delta_+, \hat{R} \geq R_+$ are violated, we can still use bound (7.44) with quantities $\hat{\delta}, \hat{\Delta}, \hat{R}$ that fall outside the intervals being replaced in its right-hand side by the corresponding upper bound $\delta_+, \Delta_+, R_+$. It is easy to check that the inequality of the theorem still holds in this case with a proper constant $C$.

It now remains to replace $s$ by $s + 3$ (so that $P(E) \geq 1 - 10e^{-s-\gamma} \geq 1 - e^{-s}$) to get that the bound of the theorem holds with probability at least $1 - e^{-s}$.

### 7.4. Proof of Theorem 3.1.

Most of the necessary ingredients have been already developed in the proof of Theorem 3.2. Let $(\lambda, \pi)$ be a couple that minimizes the right-hand side of bound (3.3). As before, if the infimum is not attained, the proof can be easily modified. We also have that (plugging $(0, \Pi f_* \pi)$ in the right-hand side of (3.3))

$$\|f_{\lambda, \pi} - f_*\|_{L_2(\Pi)}^2 \leq \|f_* - \Pi f_*\|_{L_2(\Pi)}^2, \quad \|\lambda\|_1 \leq \frac{2}{3} \frac{\|f_* - \Pi f_*\|_{L_2(\Pi)}^2}{\epsilon}.$$
holds on the event $E$ (defined in the proof of Theorem 3.2) of probability at least $\geq 1 - 10e^{-s}$, where

$$\widetilde{\delta} := \| f_0^L - f_0^\lambda \|_{L_2(\Omega)} \leq \| f_{\tilde{\lambda}, \tilde{a}} - f_{\overline{\lambda}, \overline{a}} \|_{L_2(\Omega)}$$

and we assume that bounds (7.36) hold. Using the inequalities $\gamma_2(\rho) \leq S(\mathbb{T})$, $\tilde{\Delta} \leq \tilde{R}$ and choosing $L$ to be the trivial subspace of dimension 0, we get

$$\begin{align*}
(P_n - P)\eta(f_{\tilde{\lambda}, \tilde{a}} - f_{\overline{\lambda}, \overline{a}}) + (\Pi - \Pi_n)(f_{\tilde{\lambda}, \tilde{a}} - f_{\overline{\lambda}, \overline{a}})^2 & \leq \frac{1}{8}\tilde{\delta}^2 + C\tilde{\delta}^2 \sqrt{\frac{\tilde{\delta}}{n}} + C\sigma_Y(\|\tilde{\lambda}\|_1 + \|\tilde{\epsilon}\|_1) \frac{S(\mathbb{T})}{\sqrt{n}} \\
& \quad + C \frac{\|\tilde{\lambda}\|_1^2 S^2(\mathbb{T})}{n} + C \frac{\sigma_Y^2}{n}.
\end{align*}$$

Substituting (7.54) and (7.52) back in (7.51), we get that with some $C > 0$

$$\begin{align*}
\| f_{\tilde{\lambda}, \tilde{a}} - f_* \|_{L_2(\Omega)}^2 + \| f_{\tilde{\lambda}, \tilde{a}} - f_{\overline{\lambda}, \overline{a}} \|_{L_2(\Omega)}^2 + \| \tilde{\lambda} \|_1 & \leq \| f_{\overline{\lambda}, \overline{a}} - f_* \|_{L_2(\Omega)}^2 \\
& \quad + \frac{1}{4} \| f_{\tilde{\lambda}, \tilde{a}} - f_{\overline{\lambda}, \overline{a}} \|_{L_2(\Omega)}^2 + C \| f_{\tilde{\lambda}, \tilde{a}} - f_{\overline{\lambda}, \overline{a}} \|_{L_2(\Omega)}^2 \sqrt{\frac{\tilde{\delta}}{n}} \\
& \quad + C\sigma_Y(\|\tilde{\lambda}\|_1 + \|\tilde{\epsilon}\|_1) \frac{S(\mathbb{T})}{\sqrt{n}} + C \frac{\|\tilde{\lambda}\|_1^2 S^2(\mathbb{T})}{n} + C \frac{\sigma_Y^2}{n}.
\end{align*}$$

If the constant $D$ in condition (3.2) is large enough, we have $C\sigma_Y S(\mathbb{T})/\sqrt{n} \leq \varepsilon/4$ and, since $\|\tilde{\lambda}\|_1 \leq 2\|f_* - \Pi f_*\|_{L_2(\Omega)}^2/3\varepsilon \leq 2\varepsilon^2/3\varepsilon$,

$$C \frac{\|\tilde{\lambda}\|_1^2 S^2(\mathbb{T})}{n} \leq C\varepsilon\|\tilde{\lambda}\|_1 \frac{2\|f_* - \Pi f_*\|_{L_2(\Omega)}^2 S^2(\mathbb{T})}{3\varepsilon^2 n} \leq \frac{\varepsilon}{4}\|\tilde{\lambda}\|_1.$$ 

Moreover, if $C\sqrt{\tilde{\delta}/n} \leq 3/4$, (7.55) yields

$$\| f_{\tilde{\lambda}, \tilde{a}} - f_* \|_{L_2(\Omega)}^2 + \frac{3}{4} \| \tilde{\lambda} \|_1^2 \leq \| f_{\overline{\lambda}, \overline{a}} - f_* \|_{L_2(\Omega)}^2 + \frac{3}{2} \| \tilde{\lambda} \|_1 + C \frac{\sigma_Y^2}{n}.$$

The case when (7.36) does not hold can be handled exactly as at the end of the proof of Theorem 3.2.

### 7.5. Proof of Proposition 4.2

For simplicity, we consider the case $d = 1$. Extension to arbitrary dimension follows the same proof pattern.

Note that by (4.2),

$$\text{Var} \left( \sum_{j=1}^N u_j X(t_j) \right) = \sum_{1 \leq j, \ell \leq N} k(t_j - t_\ell) u_j u_\ell = \int_{\mathbb{R}} \left| \sum_{j=1}^N e^{t_j z} u_j \right|^2 v(z) dz.$$
Clearly, the function \( q(z) = | \sum_{j=1}^{N} e^{it_{j}z} u_{j} |^{2} \) is periodic with period \( 2\pi N \); let \( I := \int_{-\pi N}^{\pi N} q(z)v(z)dz \) and \( 0 \neq m \in \mathbb{Z} \). Together with (4.4), this gives

\[
\int_{2\pi m N - \pi N}^{2\pi m N + \pi N} q(z)v(z)dz = \int_{2\pi m N - \pi N}^{2\pi m N + \pi N} q(z)v(z - 2\pi m N) \frac{v(z)}{v(z - 2\pi m N)} dz \\
\leq \sup_{|y - 2\pi m N| \leq \pi N} \frac{v(y)}{v(2\pi m N)} \int_{-\pi N}^{\pi N} q(z)v(z)dz \leq \frac{C}{(|m| - 1/2)^{2}} \cdot I.
\]

Hence

\[
\int_{-\pi N}^{\pi N} \left| \sum_{j=1}^{N} e^{it_{j}z} u_{j} \right|^{2} v(z)dz \leq \int_{-\pi N}^{\pi N} \left| \sum_{j=1}^{N} e^{it_{j}z} u_{j} \right|^{2} v(z)dz \\
\leq C \sum_{m \in \mathbb{Z}} \frac{1}{(|m| - 1/2)^{2}} \int_{-\pi N}^{\pi N} \left| \sum_{j=1}^{N} e^{it_{j}z} u_{j} \right|^{2} v(z)dz.
\]

Recall that our goal is to bound \( \| \vec{w} \|_{K} \) for \( \vec{w} \in \partial |\lambda| \) where \( \lambda \in \mathbb{R}^{N} \). It will be convenient to represent \( \vec{w} = (w(t_{1}), \ldots, w(t_{N}))^{T} \) as a restriction of a smooth, compactly supported function \( w(t), \ t \in \mathbb{R} \) on a grid \( G_{N} \). Clearly, \( w(t) \) is not unique, and we will be interested in the interpolation of “minimal energy”, as explained below.

Note that the map

\[ \ell_{2}(\mathbb{Z}) \ni x \mapsto \vec{x}_{N} \in L_{2}([-\pi N, \pi N], dy), \quad \vec{x}_{N}(y) := \frac{1}{\sqrt{2\pi N}} \sum_{j \in \mathbb{Z}} x_{j} e^{iyj/N} \]

is an isometry. With the convention \( u_{j} = 0, \ j \notin \{1, \ldots, N\} \), this implies

\[
\langle \vec{w}, \vec{u} \rangle_{2} = \sum_{j \in \mathbb{Z}} w(j) e^{\frac{2\pi j}{N}} u_{j} = \langle \vec{w}_{N}, \vec{u}_{N} \rangle_{L_{2}([-\pi N, \pi N], dy)} \\
= \frac{1}{\sqrt{N}} \left( \int_{-\pi N}^{\pi N} |\vec{w}_{N}(y)|^{2} dy \right)^{1/2} \left( \int_{-\pi N}^{\pi N} |\vec{u}_{N}(y)|^{2} v(y)dy \right)^{1/2} \\
\leq C \left( \int_{-\pi N}^{\pi N} (1 + y^{2})^{2} |\vec{w}_{N}(y)|^{2} dy \right)^{1/2} \left( \int_{-\pi N}^{\pi N} |\vec{u}_{N}(y)|^{2} v(y)dy \right)^{1/2},
\]

hence by (7.56)

\[
\| \vec{w} \|_{K}^{2} \leq C \frac{\pi N}{-\pi N} \int_{-\pi N}^{\pi N} (1 + y^{2})^{2} |\vec{w}_{N}(y)|^{2} dy.
\]

*J.E.P. — M., 2014, tome I*
Next, define $w_N(y) := \frac{1}{\sqrt{2\pi N}} \int_{-\pi N}^{\pi N} e^{-ity} \hat{w}_N(t) dt$. A simple direct computation gives

$$w_N(y) = \sum_{j \in \mathbb{Z}} w\left(\frac{2\pi j}{N}\right) \text{sinc}(\pi N(y - j/N)),$$

where $\text{sinc}(x) = (\sin x)/x$. In other words, $w_N(y)$ is the spectral approximation of $w(y)$. Define

$$w^{(p)}_N(y) := \frac{e^{-i\pi p/2}}{\sqrt{2\pi N}} \int_{-\pi N}^{\pi N} e^{-ity} t^p \hat{w}_N(t) dt$$

(note that for $p \in \mathbb{N}$ this is just the $p$th derivative of $w_N(y)$). By the isometric property of Fourier transform, this gives

$$\frac{1}{N} \int_{-\pi N}^{\pi N} t^{2p} |\hat{w}_N(t)|^2 dt = C \int_{\mathbb{R}} |w^{(p)}_N(t)|^2 dt,$$

hence (7.57), together with the triangle inequality, implies

$$\|w\|^2_K \leq C_1 \|w_N\|^2_\mathcal{W}^{2,p}(\mathbb{R}) \leq 2C_1 \left(\|w\|^2_\mathcal{W}^{2,p}(\mathbb{R}) + \|w - w_N\|^2_\mathcal{W}^{2,p}(\mathbb{R})\right).$$

We will need the following important fact (it will be used for $m = p$):

**Theorem 7.1** ([3], Theorem 5.4). — Assume that $w \in \mathcal{W}^{2,p}(\mathbb{R})$ and $m \leq p$. Then

$$\|w^{(m)}_N - w^{(m)}\|_{L_2(\mathbb{R})} \leq C(p,m)N^{-p-m} \|w\|_{\mathcal{W}^{2,p}(\mathbb{R})},$$

where $C(p, m)$ is independent of $w$ and $N$.

Together with (7.58) this implies the claim of the proposition.

7.6. Proofs of Theorems 6.1, 6.2 and 6.3. — Recall that for every $\lambda \in \mathbb{D}_\Delta$, for each $j \in J_\lambda$ we either have that $\lambda(t) \geq 0$ for all $t \in T_j$ (in this case, set $\sigma_j = +1$), or $\lambda(t) \leq 0$ for all $t \in T_j$ (set $\sigma_j = -1$). Clearly, the function

$$w := \sum_{j \in J_\lambda} \sigma_j I_{T_j}$$

satisfies the conditions $|w(t)| \leq 1$, $t \in \mathbb{T}$ and $w(t) := \text{sign}(\lambda(t))$ if $\lambda(t) \neq 0$. Therefore, $w \in \partial\|\lambda\|_1$. In what follows, we will use such $w$ as a version of subgradient of $\lambda \in \mathbb{D}_\Delta$.

We will start by providing upper bounds on RKHS-norms of $w_j$, $j \in J_\lambda$.

**Lemma 7.7.** — Suppose that, for each $j = 1, \ldots, N$, the set $T_j$ is contained in a ball $B(t_j; r)$ with some center $t_j \in \mathbb{R}^d$ and of radius $r$. Suppose also that

$$w_j(t) \geq \frac{c}{(1 + |t|^2)^p}, \quad t \in \mathbb{R}^d, \quad j = 1, \ldots, N.$$  

Then

$$\|w_j\|_{K_j} \leq Cr^{d/2}(1 + r^{-p}), \quad j \in J_\lambda.$$
Proof. — Note that for arbitrary functions $w_j$ defined on $T_j$,
\begin{equation}
\|w_j\|_{K_j} \leq C \inf_{\tilde{w}_j \in \Omega(w_j)} \|\tilde{w}_j\|_{W^{2,p}(\mathbb{R}^d)},
\end{equation}
where $\Omega(w_j)$ is the set of all extensions of $w_j$ onto $\mathbb{R}^d$ (see Proposition 4.1). To control the RKHS-norms of $w_j$, consider an arbitrary nonnegative $C^\infty$-function $\phi$ supported in the unit ball $\{t : |t| \leq 1\}$ such that $\int_{\mathbb{R}^d} \phi(t)dt = 1$. Denote $\phi_r(t) := r^{-d} \phi(t/r)$ and let
\[ \tilde{w}_j(t) := \sigma_j \int_{\mathbb{R}^d} \phi_r(t-s)I_{B(t,2r)}(s)ds = \sigma_j (\phi_r * I_{B(t,2r)})(t), \quad t \in \mathbb{R}^d. \]
It is immediate that for $t \in T_j$, $\tilde{w}_j(t) = w_j(t)$, so, $\tilde{w}_j \in \Omega(w_j)$. Thus, we have
\[ \|w_j\|_{K_j} \leq C \|\tilde{w}_j\|_{W^{2,p}(\mathbb{R}^d)} = C \|\phi_r * I_{B(t,2r)}\|_{W^{2,p}(\mathbb{R}^d)} \leq C' \|1+|t|^2\|^{p/2}1(1+|t|^2) \tilde{w}_j(t)I_{B(t,2r)}\|_{L_2(\mathbb{R}^d)}. \]
Since, by an easy computation,
\[ \|I_{B(t,2r)}\|_{L_2} \leq \mu(B(t,2r)) \leq c r^d \]
and
\[ \|1+|t|^2\|^{p/2}1(1+|t|^2) \tilde{w}_j(t)I_{B(t,2r)}\|_{L_2(\mathbb{R}^d)} \leq C_2 r^{-d/2} (1+r^{-p}), \]
we conclude that $\|w_j\|_{K_j} \leq C r^d/2 (1+r^{-p})$, $j \in J_A$ for some constant $C$. \hfill \Box

The next lemma provides bounds on $S(T, d_X)$ and $\gamma_2(\delta; d_X)$.

**Lemma 7.8.** — Let $T$ be a bounded measurable subset of $\mathbb{R}^d$ and let $X(t)$, $t \in \mathbb{R}^d$ be a centered subgaussian stationary random field with spectral measure $\nu$ and spectral density $v$. Suppose that bound (6.1) holds for some $R \geq 1$. Suppose also that
\begin{equation}
v(t) \leq \frac{B}{(1+|t|^2)^p} \]
for some $p > d/2, B > 0$. Then, there exists a constant $C > 0$ depending on $d, p, B$ such that
\[ S(T, d_X) \leq C \sqrt{\log N \vee |\log r|} \]
and
\[ \gamma_2(T, d_X; \delta) \leq C \delta \sqrt{\log CR^{(p-d/2)/2}} \sqrt{\log N}. \]

**Proof.** — By the spectral representation of covariance, for all $t_1, t_2 \in \mathbb{R}^d$ and for $A > 0$,
\begin{equation}
d^2_X(t_1, t_2) = \text{Var}(X(t_1) - X(t_2)) = \int_{\mathbb{R}^d} v(t_1 - t_2, s) - 1^2 v(s)ds \leq B|t_1 - t_2|^2 \int_{|s| \leq A} \frac{|s|^2}{(1+|s|^2)^p}ds + B \int_{|s| > A} \frac{1}{(1+|s|^2)^p}ds.
\end{equation}
If $2p > d + 2$, we take $A = \infty$ and get $d_X^2(t_1, t_2) \leq C'|t_1 - t_2|^2$ for some $C' > 0$ that depends on $p$ and $d$. If $2p = d + 2$, a simple computation of the integrals in the right-hand side of (7.62) and minimizing the resulting bound with respect to $A$ yields
$$
 d_X^2(t_1, t_2) \leq C'|t_1 - t_2|^2 \left( \log \left( \frac{1}{|t_1 - t_2|} \right) \vee 1 \right).
$$
Finally, if $2p < d + 2$, then a similar argument yields the bound
$$
 d_X^2(t_1, t_2) \leq C'|t_1 - t_2|^{2p - d}. 
$$
Using bound (6.1), it is easy to show that in each of these three cases we have
$$
 \log N(T; d_X; \varepsilon) \leq C \left( \log \frac{CR^{(p-d/2)\land 1}}{\varepsilon} \lor \log N \right), \quad \varepsilon \in (0, CR^{(p-d/2)\land 1}).
$$
The bound on $\gamma_2(T; d_X; \delta)$ now follows by controlling the generic chaining complexity in terms of Dudley’s entropy integral. We also have that, under condition (7.61), the diameter $D(T; d_X)$ admits the following estimate:
$$
 D^2(T; d_X) \leq 2 \sup_{t \in T} \text{Var}(X(t)) = 2 \int_{\mathbb{R}^d} v(s) ds \leq C'',
$$
where $C''$ is a constant depending on $d, p, B$. The bound on $S(T; d_X)$ now follows from the bound on $\gamma_2(T; d_X; \delta)$ by substituting $\delta = \sqrt{C''}$.

We will also need a bound on Kolmogorov’s width of the set of random variables $X_T$ given in the following lemma.

**Lemma 7.9.** — Let $T$ be a bounded measurable subset of $\mathbb{R}^d$ satisfying condition (6.1) and let $X(t), t \in \mathbb{R}^d$ be a centered subgaussian stationary random field with spectral measure $\nu$ and spectral density $v$. Suppose that
$$
 v(t) \leq \frac{B}{(1 + |t|^2)^p}
$$
for some $p > d/2$, $B > 0$. Then, there exists a constant $C > 0$ depending only on $d, p$ and $B$ such that for all $m \geq CN$
$$
 \rho_m(X_T) \leq C \left( \frac{R}{m^{1/p}} \right)^{p-d/2}. 
$$

**Remark 7.2.** — Note that bound (7.64) is sharp (up to a constant). A matching lower bound can be proved via an argument based on replacing the spectral density $v$ by a smaller density $\tau$ that is constant in a cube of a proper size and zero outside of the cube. For such a smaller density, it is possible to find a grid of points of sufficiently large cardinality $m$ such that the values of the stationary random field with spectral density $\tau$ at the points of the grid are uncorrelated. Bounding the corresponding Kolmogorov’s width from below can be now reduced to bounding Kolmogorov numbers of the embedding of $\ell_1^m$ into $\ell_2^m$, see Gluskin [18] for the solution of the last problem.

The authors are very thankful to M. Lifshits for pointing out this beautiful argument.
Proof: — We will construct an approximation of the set of random variables $X_T = \{X(t) : t \in \mathbb{T}\}$ by a finite dimensional subspace of subgaussian random variables $L \subset \mathcal{L}_X$. Since $X$ is a stationary random field, the following spectral representation holds

$$X(t) = \int_{\mathbb{R}^d} e^{i(t,s)}Z(ds),$$

where $Z$ is an orthogonal random measure such that

$$\mathbb{E}Z(A)\overline{Z(B)} = \nu(A \cap B), A, B \in \mathcal{B}_{\mathbb{R}^d}.$$

By a standard isometry argument, to approximate the random variable $X(t)$ in the space $L_2(\mathbb{P})$, it is enough to approximate the function $e^{2\pi i(t, \cdot)}$ in the space $L_2(\mathbb{R}^d, \nu)$. For $\delta \leq r$, consider a $\delta$-net of the set $\mathbb{T}$ that consists of $N' \leq (R/\delta)^d$ points $\tau_1, \ldots, \tau_{N'}$.

To construct an approximation of the exponential function, we will use Taylor expansion of order $l$ in a $\delta$-neighborhood of each of the points $\tau_k$. We use the following standard bound on the remainder of Taylor expansion:

$$\left| e^{i(h,s)} - Q_l(h; s) \right| \leq \frac{|h|^l |s|^l}{l!}, \quad Q_l(h; s) := \sum_{j=0}^{l-1} \frac{i^j(h,s)^j}{j!}.$$

For $t \in B(\tau_k; \delta)$,

$$e^{i(t,s)} = e^{i(\tau_k,s)}e^{i(t-\tau_k,s)} = e^{i(\tau_k,s)}Q_l(t-\tau_k; s) + e^{i(\tau_k,s)}(e^{i(t-\tau_k,s)} - Q_l(t-\tau_k; s)).$$

Denote (for some $A > 0$ to be chosen later)

$$\zeta_l^{(k)}(h) := \text{Re}\left( \int_{\mathbb{R}^d} e^{i(\tau_k,s)}Q_l(h; s)I(|s| \leq A\delta^{-1})Z(ds) \right).$$

By spectral isometry (using the fact that $X$ is real valued), we get that for all $k = 1, \ldots, N'$ and all $t \in B(\tau_k; \delta)$ (thus, for all $t \in \mathbb{T}$)

$$\left| \zeta_l^{(k)}(t-\tau_k) \right|^2 \leq \mathbb{E} \left| X(t) - \int_{\mathbb{R}^d} e^{i(\tau_k,s)}Q_l(h; s)I(|s| \leq A\delta^{-1})Z(ds) \right|^2 \leq \int_{|s| \leq A\delta^{-1}} |e^{i(t,s)} - e^{i(\tau_k,s)}Q_l(t-\tau_k; s)|^2 v(s)ds + \int_{|s| > A\delta^{-1}} v(s)ds.$$

Under condition (7.63) and the assumption $p > d/2$, using (7.65), we get that with some constant $C > 0$ depending only on $B, d$ and for all $k = 1, \ldots, N'$ and $l \geq (2p - d) \vee 1$

$$\int_{|s| \leq A\delta^{-1}} |e^{i(t,s)} - e^{i(\tau_k,s)}Q_l(t-\tau_k; s)|^2 v(s)ds \leq \frac{\delta^{2l}}{(l!)} \int_{|s| \leq A\delta^{-1}} |s|^{2l} v(s)ds \leq B \frac{\delta^{2l}}{(l!)} \int_{|s| \leq A\delta^{-1}} \frac{|s|^{2l}}{(1 + |s|^2)^p} ds \leq C \frac{\delta^{2p-d}}{A^{2p-d-2l}(2l - 2p + d)(l!)^2}. $$
We also have
\[
\int_{|s| > A5^{-1}} v(s) ds \leq B \int_{|s| > A5^{-1}} \frac{1}{(1 + |s|^2)^p} ds \leq C \frac{\delta^{2p-d}}{(2p-d)A^{2p-d}}.
\]
We will now set
\[
A := A_l := (2l)^{1/(2l)} (l!)^{1/l}.
\]
Then, (7.66) easily implies that with some constant \( C \) depending only on \( p \) and \( d \)
\[
\mathbb{E}[X(t) - \zeta_t^{(k)}(t - \tau_k)]^2 \leq C \left( \frac{\delta}{A_l} \right)^{2p-d}.
\]
Using Stirling’s approximation, it is easy to see that \( A_l \geq l/e \), implying that
\[
\mathbb{E}[X(t) - \zeta_t^{(k)}(t - \tau_k)]^2 \leq C \left( \frac{\delta}{l} \right)^{2p-d}.
\]
(7.67)

Note that \( Q_l(h; \cdot) \) is polynomial of degree \( l - 1 \) of \( d \) variables, hence, the family of functions
\[
\left\{ e^{i(t_k\cdot)} Q_l(h; \cdot) | | | \leq A l^{-1} : h \in \mathbb{R}^d \right\}
\]
belongs to a (complex) linear space of dimension \( (l-1+d) \leq (l + d - 1)^d \). This immediately implies that the family of random variables \( \{ \zeta_t^{(k)}(h) : h \in \mathbb{R}^d \} \) belongs to a linear subspace of \( \mathcal{L}_X \) whose dimension is at most \( 2(l + d - 1)^d \). Therefore,
\[
\left\{ \zeta_t^{(k)}(t - \tau_k) : t \in B(\tau_k; \delta), k = 1, \ldots, N' \right\}
\]
belongs to a subspace of \( \mathcal{L} \) of dimension \( \leq 2(l + d - 1)^d N' \leq 2(l + d - 1)^d (R/\delta)^d \). Let \( m \geq 2(l + d - 1)^d \) and let
\[
\delta = 2^{1/d}(l + d - 1) \frac{R}{m^{1/d}}.
\]
Assuming that \( m \geq C_1 N \), where \( C_1 := 2(l + d - 1)^d \kappa d \), we have \( \delta \leq r \). Then
\[
2(l + d - 1)^d (R/\delta)^d = m \text{ and it follows from (7.67) that}
\]
\[
\rho_m(X_T) \leq C \left( \frac{l + d - 1}{l} \right)^{p-d/2} \frac{R^{p-d/2}}{mp^{p-d/2}},
\]
with some constant \( C \) depending on \( B, d, p \). The claim of the lemma follows by substituting the smallest \( l \geq (2p-d) \lor d \). \( \square \)

We will now provide an upper bound on the “approximate dimension” \( d(w; \lambda) \) needed to complete the proof of the theorem. To this end, recall that we assume that for all \( j = 1, \ldots, N \) the set \( T_j \) belongs to a ball of radius \( r \geq N^{-1/d} \) and \( R = \kappa N^{1/d} r \), \( R \geq 2 \). Also, for an oracle \( \lambda, R(\lambda) = \kappa (N(\lambda))^{1/d} r \), so, we have \( r \leq R(\lambda) \leq R \).

In what follows, \( C, C', \text{ etc are constants depending on } B, d, p \). First, let us upper bound \( \gamma_2(\rho_m(w)) = \gamma_2(\rho_m(X_{T_n})) \). Using Lemmas 7.8 and 7.9, we get that for all \( m \geq C_1 N(\lambda) \)
\[
(7.68) \quad \gamma_2(\rho_m(w)) \leq C \left( \frac{R(\lambda)}{mp^{d/2}} \right)^{p-d/2} \sqrt{\log \left( \frac{CR^{p-d/2}mp^{d-1/2}}{(R(\lambda))^{p-d/2}} \right)} \lor \log N.
\]
Since \( R/R(\lambda) = \kappa N^{1/d_r}/\kappa(N(\lambda))^{1/2} \leq N^{1/d} \), it is easy to conclude that
\[
\gamma_2(\rho_m(w)) \leq C \frac{(R(\lambda))^{p-d/2}}{m^{p/d-1/2}} \sqrt{\log m} \sqrt{C} \frac{(R(\lambda))^{p-d/2}}{m^{p/d-1/2}} \sqrt{\log N}.
\]
To provide an upper bound on \( d(w, \lambda) \), we first find the smallest \( m \) satisfying the inequality
\[
\frac{\sigma_w^2 m}{n} \geq C \frac{\|\lambda\|_1 (R(\lambda))^{p-d/2}}{m^{p/d-1/2}} \sqrt{\log m} \sqrt{C} \frac{\|\lambda\|_1 (R(\lambda))^{p-d/2}}{m^{p/d-1/2}} \sqrt{\log N}.
\]
This is equivalent to the bound
\[
(7.69) \quad m \geq C \frac{n^{d/(2p+d)}\|\lambda\|^2_{1} (R(\lambda))^{d(2p-d)/(2p+d)}}{\sigma_w^{d/(2p+d)}} \cdot \left( \log m \right)^{d/(2p+d)} \sqrt{(\log N)^{d/(2p+d)}}
\]
Note that in the oracle inequality of Theorem 3.2, it is enough to restrict oracles \( \lambda \) to the ball
\[
\|\lambda\|_1 \leq C' \|f_r - \Pi f_r\|_{L_2(\Pi)} n^{1/2}
\]
for some constant \( C' > 0 \) (see bound (7.5) in the proof of this theorem). Recall that also
\[
N^{-1/d} \leq r \leq R(\lambda) \leq R = \kappa N^{1/d_r}.
\]
Therefore, bound (7.69) easily implies that
\[
(7.70) \quad m \geq C \frac{n^{d/(2p+d)}\|\lambda\|^2_{1} (R(\lambda))^{d(2p-d)/(2p+d)}}{\sigma_w^{d/(2p+d)}} \cdot \left( \log N \wedge \log n \wedge \log \sigma_w \wedge \log r \right)^{d/(2p+d)}
\]
It easily follows from the definition of \( d(w, \lambda) \) that either we have \( d(w, \lambda) \leq C_1 N(\lambda) \), or \( d(w, \lambda) \leq m \) for any \( m \) satisfying (7.70). Therefore, with some constant \( C > 0 \)
\[
(7.71) \quad d(w; \lambda) \leq C N(\lambda)
\]
\[
\sqrt{C} \frac{n^{d/(2p+d)}\|\lambda\|^2_{1} (R(\lambda))^{d(2p-d)/(2p+d)}}{\sigma_w^{d/(2p+d)}} \cdot \left( \log N \wedge \log n \wedge \log \sigma_w \wedge \log r \right)^{d/(2p+d)}
\]
To complete the proof, it is enough to substitute this bound on \( d(w; \lambda) \) in the oracle inequality of Theorem 3.2. Bounds (5.1) and Lemma 7.7 should be used to control the alignment coefficient \( a(w) \).

As to the proof of Theorem 6.2, the main difference is in the bounds on the alignment coefficient \( a(w) \). For a given oracle \( \lambda \in \mathcal{D} \), and a covering \( B(t_1; r), \ldots, B(t_{N(\lambda)}; r) \) of \( \text{supp}(\lambda) \), let \( \sigma_j \) be the sign of \( \lambda \) on \( B(t_j; r) \cap \text{supp}(\lambda) \) and \( \tilde{w}_j := \sigma_j (\phi_r * I_{B(t_j; 2r)}) \), \( j = 1, \ldots, N(\lambda) \) (see the notations of the proof of Lemma 7.7). It is easy to see that \( \sum_{j \in J_\lambda} \tilde{w}_j \) is an extension of a subgradient \( w \in \partial\|\lambda\|_1 \). Thus, by
Proposition 4.1, 
\[ a^2(\omega) \leq \|w\|^2_{\mathcal{K}} \leq \left\| \sum_{j=1}^{N(\lambda)} \tilde{w}_j \right\|^2_{\mathcal{W}_2,p}. \]

Since functions \( \tilde{w}_j \) have disjoint support, we can further bound this using Proposition A.2 and of Lemma 7.7 as 
\[ a^2(\omega) \leq C \left[ \sum_{j=1}^{N(\lambda)} \|\tilde{w}_j\|_{\mathcal{W}_2,p}^2 + \frac{1}{r^{2d}} \sum_{j=1}^{N(\lambda)} \|\tilde{w}_j\|_{\mathcal{W}_2,p}^2 \right] \leq C \left( r^d + r^{d-2p} \right) N(\lambda). \]

Finally, to prove the result of Theorem 6.3, we need to bound the alignment coefficient \( a(\omega) \) as follows. Let \( \phi \) be an arbitrary nonnegative \( C^\infty \)-function supported in the unit ball \( \{ t : |t| \leq 1 \} \) such that for all \( t \in \mathbb{R}^d \), \( \phi(t) \leq \phi(0) = 1 \). Given \( \lambda \in \mathbb{D} \) and \( r \leq \delta(\lambda) \), let 
\[ \tilde{w}_j = \text{sign}(\lambda_j) \phi \left( \frac{t - L_j}{r} \right), \quad j \in J(\lambda). \]

Clearly, restriction of \( w = \sum_{j \in J(\lambda)} \tilde{w}_j \) to the grid \( \mathcal{G}_N \) is an element of \( \partial \| \lambda \|_1 \). By Proposition 4.2, we have 
\[ a^2(\omega) \leq \|w\|^2_{\mathcal{K}} \leq \left\| \sum_{j=1}^{N(\lambda)} \tilde{w}_j \right\|^2_{\mathcal{W}_2,p}. \]

By Proposition A.2 and a simple computation is spirit of Lemma 7.7 
\[ a^2(\omega) \leq C \left( r^d + r^{d-2p} \right) N(\lambda). \]

It is easy to see that \( \gamma_2(\rho_m(\omega)) \) and \( d(\omega; \lambda) \) can be bounded above by their “continuous” counterparts \( \Gamma = [0, 2\pi)^d \), in particular, inequalities \((7.68)\) and \((7.71)\) hold. To complete the proof, it is enough to substitute bounds on \( d(\omega; \lambda) \) and \( a^2(\omega) \) in the oracle inequality of Theorem 3.2 and optimize the resulting expression with respect to \( r \). Choose \( r_\ast(\lambda) \) as \( r_\ast(\lambda) = \min(\tilde{r}, \delta(\lambda)) \) with \( \tilde{r} \) defined as 
\[ \tilde{r}^{2p-d} = \left( \frac{N(\lambda)^2}{n} \right)^{d/(2p+2d)} \frac{\sigma^{2d/(p+1)} \sigma^{(2p+d)/(2p+2d)}}{(L\|\lambda\|_2)^{d/(2p+2d)}}, \]

where \( L = \log n \lor \log N \lor |\log \sigma_Y| \). The claim now follows from simple algebra.

Appendix A. Technical background and remaining proofs

A.1. Existence of solutions of optimization problems. — We provide below sufficient conditions for existence of solutions to the problems \((2.3)\) and \((1.2)\).

Theorem A.1. — Let \( \mathbb{D} \) be a convex, weakly compact subset of \( L_1(\mu) \). Then 
1. \( F(\lambda, a) \), \( F_n(\lambda, a) \) are weakly lower semicontinuous; 
2. Solutions to problems \((2.3)\) and \((1.2)\), denoted by \( \lambda_\varepsilon \) and \( \tilde{\lambda}_\varepsilon \), exist.
Proof: We prove the statement for $F(\lambda)$, and the result for $F_n(\lambda)$ follows similarly. The functional $\lambda \mapsto \|\lambda\|_1$ is continuous. Assume $\|\lambda_k - \lambda_0\|_1 \to 0$. Using Hölder’s inequality, we get

$$P(\ell \cdot f_{\lambda_k, a(\lambda_k)}) - P(\ell \cdot f_{\lambda_0, a(\lambda_0)}) = \mathbb{E}(Y - f_{\lambda_k, a(\lambda_k)}(X))^2 - \mathbb{E}(Y - f_{\lambda_0, a(\lambda_0)}(X))^2$$

$$\leq \mathbb{E} \left[ (2Y - f_{\lambda_k, a(\lambda_k)}(X) - f_{\lambda_0, a(\lambda_0)}(X)) \int (\lambda_0 - \lambda_k)(X - \mathbb{E}X) d\mu \right]$$

$$\leq \mathbb{E}^{1/2} \left( \int (\lambda_0 - \lambda_k)(X - \mathbb{E}X) d\mu \right)^2 \mathbb{E}^{1/2} (2Y - (f_{\lambda_k, a(\lambda_k)} + f_{\lambda_0, a(\lambda_0)})(X))^2$$

$$\leq \|\lambda_k - \lambda_0\|_{1}^{2/2} \|X - \mathbb{E}X\|_\infty^2 \left( 2\sqrt{\text{Var}(Y)} + \|\lambda_k + \lambda_0\|_1 \mathbb{E}^{1/2} \|X - \mathbb{E}X\|_\infty^2 \right) \to 0,$$

where in the last step we used the fact that

$$\left| \int T \mathbb{E}(\lambda(t)(X(t) - \mathbb{E}X(t)) \mu(dt) \right| \leq \|\lambda\|_1 \sup_{t \in T} |X(t) - \mathbb{E}(X(t))|.$$

Thus, $F(\lambda)$ is continuous, hence it is lower semi-continuous. In turn, this is equivalent to the fact that the level sets $\mathcal{L}_t = \{\lambda : F(\lambda) \leq t\}$ are closed. Moreover, they are convex since $F$ is. Mazur’s theorem (see [29], Theorem 2.1) implies that they are also closed in weak topology, so $F$ is weakly lower semi-continuous.

Now it is easy to show existence of solutions. Given a minimizing sequence $\{\lambda_k\} \subseteq \mathbb{D}$, we can extract a weakly convergent subsequence

$$\lambda_{k_l} \stackrel{\sigma}{\to} \lambda_\infty.$$

It remains to note that by weak compactness and lower semi-continuity $\lambda_\infty \in \mathbb{D}$ and $-\infty < F(\lambda_\infty) \leq \liminf_{l \to \infty} F(\lambda_{k_l})$, which means that $\lambda_\infty$ is the solution. \hfill \Box

When $\mathbb{T}$ is finite, then one can clearly take $\mathbb{D} = L_1(\mathbb{T}, \mu) \subseteq \mathbb{R}^{\mathbb{T}}$, and Theorem A.1 is not needed to prove existence of $\lambda_\infty$. However, in general the unit ball in $L_1(\mathbb{T}, \mu)$ is not weakly compact, so one way to proceed is to choose $\mathbb{D}$ to be uniformly integrable (which implies weak compactness, see Theorem 4.7.18 in [7]). A possible choice is

$$\mathbb{D} = \left\{ \lambda : \left| \int T \max (|\lambda(t)| \log |\lambda(t)|, 0) d\mu(t) \right| \leq L \right\}$$

for some $L > 0$.

A.2. Orlicz norms. Let $\psi : \mathbb{R}_+ \to \mathbb{R}_+$ be a convex nondecreasing function with $\psi(0) = 0$.

Definition A.1. The Orlicz norm of a random variable $\eta$ on a probability space $(\Omega, \Sigma, \mathbb{P})$ is defined via

$$\|\eta\|_{\psi} := \inf \{ C > 0 : \mathbb{E}\psi(|\eta|/C) \leq 1 \}$$
By \( \| \cdot \|_{\psi_1} \), \( \| \cdot \|_{\psi_2} \) we denote the Orlicz norms for \( \psi_1(x) := e^x - 1 \) and \( \psi_2(x) := e^{x^2} - 1 \), respectively; the following inequalities are elementary:

(A.1) \[ \| \eta \|_{\psi_1} \leq \sqrt{\log 2} \| \eta \|_{\psi_2}, \]

(A.2) \[ \| \eta^2 \|_{\psi_1} = \| \eta \|_{\psi_2}^2, \]

(A.3) \[ \| \xi \eta \|_{\psi_1} \leq \| \xi \|_{\psi_2} \| \eta \|_{\psi_2}. \]

It is easy to check from the definition that every subgaussian random variable (meaning that \( \mathbb{E} e^{s \eta} \leq e^{\Gamma \sigma^2 \eta^2}, s \in \mathbb{R} \)) satisfies the following property:

(A.4) \[ \| \eta \|_{\psi_2}^2 \leq 8 \Gamma \sigma^2. \]

In what follows, we use the same notations for Orlicz norms on other probability spaces (for instance, \( C_{bu}(T; dX) \) with its Borel \( \sigma \)-algebra and probability measure \( \Pi \)).

### A.3. Bounds for subgaussian processes and Talagrand’s generic chaining complexities

**Theorem A.2.** Let \( \{Z(t), t \in T\} \) be a centered subgaussian process. Then, for all \( u \geq 0 \), \( t_0 \in T \),

1. \( \mathbb{P}(\sup_t (Z(t) - Z(t_0)) \geq 2u \cdot \gamma_2(T, dZ)) \leq Ce^{-u^2/4}, \)
2. \( \mathbb{E}\|Z\|_{\infty} \leq \mathbb{E}|Z(t_0)| + L\gamma_2(T, dZ), \)

where \( d_Z(t, s) = \sqrt{\text{Var}(Z(t) - Z(s))} \).

**Proof.** See Chapter 1.2 in [39]. \( \square \)

A simple corollary is the following inequality:

(A.5) \[ \mathbb{P}(\|Z\|_{\infty} \geq C \sqrt{\gamma_2(T, dZ)} + \inf_{t \in T} \sqrt{\text{Var}(Z(t))}) \leq e^{-t}. \]

We mention another result which is useful in our investigation:

**Proposition A.1.** Let \( Z \) be a centered subgaussian stochastic process such that \( \gamma_2(T, dZ) < \infty \) and let \( Z_1, \ldots, Z_n \) be iid copies of \( Z \). Then for any \( t_0 \in T \),

1. \( (\log 2)^{-1/2} \|\|Z\|_{\infty}\|_{\psi_1} \leq \|\|Z\|_{\infty}\|_{\psi_2} \leq \|Z(t_0)\|_{\psi_2} + L\gamma_2(T, dZ), \)
2. \( \| \max_{j=1 \ldots n} \|Z_j\|_{\infty}\|_{\psi_1} \leq C \log n \|\|Z\|_{\infty}\|_{\psi_1}. \)

**Proof.** First statement is a straightforward corollary of Talagrand’s result and integration-by-parts formula. For the proof of the second claim, see [41], Lemma 2.2.2. \( \square \)

In the case when \( Z(t), t \in T \) is a centered Gaussian process, a famous result of Talagrand (see Theorem 2.1.1 in [39]) states that

(A.6) \[ \frac{1}{K} \gamma_2(T; dZ) \leq \mathbb{E}\sup_{t \in T} Z(t) \leq K\gamma_2(T; dZ). \]
for some universal constant $K$. Moreover, the upper bound also holds for the centered subgaussian process $Z$.

In practice, a useful way to estimate the generic chaining complexity $\gamma_2(T; d_Z)$ and its “local version” $\gamma_2(\delta)$ is to evaluate Dudley’s entropy integral:

**Theorem A.3.** — The following inequality holds for all $\delta \leq \sup_{t, s \in T} d_X(t, s)$:

$$\gamma_2(\delta) \leq (2\sqrt{2} - 1)^{-1} \int_0^\delta \sqrt{\log N(T, d_Z, \varepsilon/4)} \, d\varepsilon,$$

where $N(T, d_Z, \varepsilon)$ is the minimal number of balls of radius $\varepsilon$ required to cover $T$.

**Proof.** — This well-known bound can be obtained by repeating the argument of Proposition 1.2.1 in [39]. □

The following immediate corollary covers two important examples.

**Corollary A.1**

1. If $\text{Card}(T) = N$, then
   $$\gamma_2(\delta) \leq C\delta \sqrt{\log N};$$

2. If the covering numbers grow polynomially, i.e. $N(T, d_X, \varepsilon) \leq C_1 (A/\varepsilon)^V$, then
   $$\gamma_2(\delta) \leq C_2 \delta \sqrt{V \log(A/\delta)}.$$

**A.4. Empirical processes.** — We state a version of generic chaining bounds for empirical processes due to S. Mendelson, S. Dirksen and W. Bednorz which are used in our proofs. Let $F$ be a class of functions defined on a measurable space $(S, \mathcal{A})$. Suppose $F$ is symmetric, that is, $f \in F$ implies $-f \in F$ (in applications, we often deal with the classes that do not satisfy this assumption and then replace $F$ by $F \cup -F$). Let $(X_1, \xi), (X_2, \xi), \ldots, (X_n, \xi)$ be i.i.d. random variables with values in $S \times \mathbb{R}$ such that $E f(X) = 0$, $f \in F$ and $\xi$ is a subgaussian random variable. Let $\Pi$ be the marginal distribution of $X$. It will be used as a measure on $(S, \mathcal{A})$.

**Theorem A.4.** — There exists an absolute constant $C > 0$ such that

$$\mathbb{E} \sup_{f \in F} \left| n^{-1} \sum_{j=1}^n \xi_j f(X_j) - E f(X) \right| \leq C \left[ \|\xi\|_{\psi_2} \frac{\gamma_2(F; \psi_2)}{\sqrt{n}} \sqrt{\frac{\gamma_2^2(F; \psi_2)}{n}} \right].$$

This inequality follows from Corollary 3.9 in [32]. We will often combine it with a version of Talagrand’s concentration inequality for unbounded function classes due to Adamczak [1] (stated in a convenient form for our purposes). Let $F$ be a class of functions defined on a measurable space $(S, \mathcal{A})$ and let $X_1, \ldots, X_n$ be i.i.d. random variables sampled from distribution $P$ on $(S, \mathcal{A})$. Let $F$ be a measurable
envelope for $\mathcal{F}$, that is $F$ is a measurable function on $S$ such that $|f(x)| \leq F(x)$, $x \in S$, $f \in \mathcal{F}$. Then, there exists a universal constant $K > 0$ such that

$$
\text{(A.7)} \quad \sup_{f \in \mathcal{F}} \left| \frac{1}{n} \sum_{j=1}^{n} f(X_j) - \mathbb{E}f(X) \right| \leq K \left[ \mathbb{E} \sup_{f \in \mathcal{F}} \left| \frac{1}{n} \sum_{j=1}^{n} f(X_j) - \mathbb{E}f(X) \right| ight]
+ \sup_{f \in \mathcal{F}} \sqrt{\text{Var}(f(X))} \sqrt{\frac{s}{n}} + \left\| \max_{1 \leq j \leq n} |F(X_j)| \right\|_\psi \frac{s}{n}
$$

with probability $\geq 1 - e^{-s}$.

Finally, we state a recent sharp bound for the empirical processes due to S. Dirksen [15] and W. Bednorz [5] (earlier versions of exponential generic chaining bounds for similar empirical processes are due to Mendelson [33], [32]). Assume that $\{f(X), f \in \mathcal{F}\}$ is a subset of the subgaussian space $\mathcal{L}$.

**Theorem A.5.** — There exists an absolute constant $C > 0$ such that

$$
\sup_{f \in \mathcal{F}} \left| n^{-1} \sum_{j=1}^{n} f^2(X_j) - \mathbb{E}f^2(X) \right| \leq C \left[ \sup_{f \in \mathcal{F}} \|f\|_{\psi_2} \frac{\gamma_2(\mathcal{F}; \psi_2)}{\sqrt{n}} + \frac{\gamma_2(\mathcal{F}; \psi_2)}{n} \right]
+ \sup_{f \in \mathcal{F}} \|f\|_{\psi_1} \left( \sqrt{\frac{2}{n}} \sqrt{\frac{s}{n}} \right)
$$

with probability $\geq 1 - e^{-s}$.

For a proof and discussion of this bound, see Theorem 5.5 in [15]. Note that in (ii), the generic chaining complexity $\gamma_2(\mathcal{F}; \psi_2)$ is the Fourier transform of $\psi_2$. It is well known that for $p \in \mathbb{Z}_+$, this coincides with another definition of Sobolev spaces (in terms of partial derivatives).

Assume that $f \in \mathbb{W}^{2,p}(\mathbb{R}^d)$ for $p \in \mathbb{Z}_+$ is such that $f = \sum_{j=1}^{k} f_j$, where $f_j$, $j = 1 \ldots k$ have disjoint supports. Clearly, in this case we have $\|f\|_{\mathbb{W}^{2,p}(\mathbb{R}^d)} = \sum_{j=1}^{k} \|f_j\|_{\mathbb{W}^{2,p}(\mathbb{R}^d)}$. When $p$ is not an integer, we will use the following proposition.

**Proposition A.2.** — Assume that $p \in \mathbb{R}_+$, $\alpha := p - [p] > 0$ and $f \in \mathbb{W}^{2,p}(\mathbb{R}^d)$ is such that $f = \sum_{j=1}^{k} f_j$, where $f_j$, $j = 1 \ldots k$, have disjoint supports and

$$
\min_{1 \leq i < j \leq k} \text{dist}(\text{supp}(f_i), \text{supp}(f_j)) \geq r > 0,
$$

where $\text{dist}$ is the Euclidean distance. Then

$$
\|f\|_{\mathbb{W}^{2,p}(\mathbb{R}^d)}^2 \leq C(d, p) \left[ \sum_{j=1}^{k} \|f_j\|_{\mathbb{W}^{2,p}(\mathbb{R}^d)}^2 + \frac{1}{r^{2\alpha}} \sum_{j=1}^{k} \|f_j\|_{\mathbb{W}^{2,p}(\mathbb{R}^d)}^2 \right].
$$
Proof: — We will need to use equivalence of certain norms defined on Sobolev spaces \( \mathbb{W}^{2,p}(\mathbb{R}^d) \). Let

\[
\|f\|_{\mathbb{W}^{2,p}(\mathbb{R}^d)}^2 := \|f\|_{\mathbb{W}^{2,p}(\mathbb{R}^d)}^2 + \max_{[m]=|p|} \iint_{\mathbb{R}^d \times \mathbb{R}^d} \left( \frac{\partial^m f(x) - \partial^m f(y)}{|x-y|^{2\alpha+d}} \right)^2 dx dy,
\]

where we use the usual multi-index notation. It is known that \( \|\cdot\|_{\mathbb{W}^{2,p}} \) and \( \|\cdot\|_{\mathbb{W}^{2,p}}' \) are equivalent (e.g., see [2] p. 219). Let \( f = \sum_{i=1}^k f_i \) satisfy the conditions of the proposition. Making the change of variables \( x = t + u, \ y = u \) in the expression of \( \|\cdot\|_{\mathbb{W}^{2,p}(\mathbb{R}^d)}' \), we have

\[
\|f\|_{\mathbb{W}^{2,p}(\mathbb{R}^d)}^2 = \|f\|_{\mathbb{W}^{2,p}(\mathbb{R}^d)}^2 + \max_{[m]=|p|} \iint_{\mathbb{R}^d \times \mathbb{R}^d} (\partial^m f(t+u) - \partial^m f(u))^2 du \frac{dt}{|t|^{2\alpha+d}}
\]

\[
= \sum_{j=1}^k \|f_j\|_{\mathbb{W}^{2,p}(\mathbb{R}^d)}^2 + \max_{[m]=|p|} \left[ \iint_{\mathbb{R}^d \times B(0,r)} (\partial^m f(t+u) - \partial^m f(u))^2 du \frac{dt}{|t|^{2\alpha+d}}
\right]
\]

\[
+ \sum_{j=1}^k \iint_{\mathbb{R}^d \times B(0,r)} (\partial^m f(t+u) - \partial^m f(u))^2 du \frac{dt}{|t|^{2\alpha+d}}
\]

It remains to notice that

\[
\iint_{\mathbb{R}^d \times B(0,r)} (\partial^m f(t+u) - \partial^m f(u))^2 du \frac{dt}{|t|^{2\alpha+d}}
\]

\[
= \sum_{j=1}^k \iint_{\mathbb{R}^d \times B(0,r)} (\partial^m f_j(t+u) - \partial^m f_j(u))^2 du \frac{dt}{|t|^{2\alpha+d}}
\]

\[
\leq \sum_{j=1}^k \iint_{\mathbb{R}^d \times \mathbb{R}^d} (\partial^m f_j(x) - \partial^m f_j(y))^2 dx dy
\]

and, since \( (f(t+u) - f(u))^2 \leq 2f^2(t+u) + 2f^2(u) \),

\[
\iint_{\mathbb{R}^d \times B(0,r)} (\partial^m f(t+u) - \partial^m f(u))^2 du \frac{dt}{|t|^{2\alpha+d}} \leq 2\|\partial^m f\|^2_{L_2(\mathbb{R}^d)} \int_{|t| \geq r} \frac{dt}{|t|^{d+2\alpha}}
\]

\[
= C_1(d, \alpha) \frac{\|\partial^m f\|^2_{L_2(\mathbb{R}^d)}}{r^{2\alpha}},
\]

where \( C_1(d, \alpha) = 2\pi^{d/2}(d+2\alpha)/\alpha \Gamma(d/2) \), and the claim easily follows. \( \square \)

A.6. Proof of Proposition 4.4. — Let \( J_1, J_2 \) be two disjoint subsets of \( \{1, \ldots, N\} \), and define

\[
r(J_1; J_2) := \sup_{u,v} \left| \frac{\langle \sum_{j \in J_1} f_{u_j}, \sum_{j \in J_2} f_{v_j} \rangle_{L_2(\Pi)}}{\sqrt{\sum_{j \in J_1} \|f_{u_j}\|^2_{L_2(\Pi)} \sum_{j \in J_2} \|f_{v_j}\|^2_{L_2(\Pi)}}} \right|
\]

J.É.P. — M., 2014, tome 1
where the supremum is taken over all
\[ u = \sum_{j \in J_1} u_j, \quad v = \sum_{j \in J_2} v_j \]
such that
\[ \text{supp}(u_j) \subseteq T_j, \quad \text{supp}(v_j) \subseteq T_j \quad \text{and} \quad \sum_{j \in J_1} \|f_{u_j}\|_{L_2(\Pi)}^2 \neq 0, \quad \sum_{j \in J_2} \|f_{v_j}\|_{L_2(\Pi)}^2 \neq 0. \]

Next, let
\[ \rho_d := \max \{ r(J_1; J_2) : J_1 \cap J_2 = \emptyset, \text{Card}(J_1) + \text{Card}(J_2) \leq 3d \}. \]

In what follows, we set \( \lambda(u_j) := \|f_{u_j}\|_{L_2(\Pi)} \) and \( h(u_j) := f_{u_j}/\|f_{u_j}\|_{L_2(\Pi)}. \)

**Lemma A.1.** — The following inequality holds: \( \rho_d \leq \delta_{3d}. \)

**Proof.** — See Lemma 2.1 in [11]. \( \square \)

Set \( J_0 := J, \lambda^{(0)} := \{ \lambda(u_j), \, j \in J_0 \}, \) and let \( \lambda(u_{\pi(1)}), \ldots, \lambda(u_{\pi_N}) \) be the vector \( \{ \lambda(u_j), \, j \in J_0 \} \) sorted in the decreasing order, so that \( \pi \) is some permutation. We further define \( J_1 := (\pi(1), \ldots, \pi(d)), \) \( J_2 := (\pi(d + 1), \ldots, \pi(2d)), \) etc., and \( \lambda^{(k)} := (\lambda(u_j), \, j \in J_k). \) Everywhere below, \( \|\cdot\|_1, \|\cdot\|_2 \) denote the usual vector \( p \)-norms.

First, we will show that
\[
\sum_{k \geq 2} \|\lambda^{(k)}\|_2 \leq b \|\lambda^{(0)}\|_2 := b \sqrt{\sum_{j \in J_0} \lambda^2(u_j)}. \tag{A.8}
\]

Indeed, for all \( j \in J_k, \, k \geq 2 \) we have \( |\lambda(u_j)| \leq \frac{1}{\sqrt{d}} \sum_{i \in J_{k-1}} |\lambda(u_i)|, \) implying that \( \|\lambda^{(k)}\|_2 \leq \frac{1}{\sqrt{d}} \|\lambda^{(k-1)}\|_1. \) Summing up, we get
\[
\sum_{k \geq 2} \|\lambda^{(k)}\|_2 \leq \frac{1}{\sqrt{d}} \sum_{j \notin J_0} |\lambda(u_j)| \leq \frac{b}{\sqrt{d}} \sum_{j \in J_0} |\lambda(u_j)|,
\]
where the last inequality follows from the definition of the cone \( C_{b,J}. \) Inequality (A.8) follows since \( \frac{b}{\sqrt{d}} \sum_{j \in J_0} |\lambda(u_j)| \leq b \sqrt{\sum_{j \in J_0} \lambda^2(u_j)}. \)
Let $P_j$ be the $L_2(\Pi)$-orthogonal projection onto $L_j$, the linear span of $\{h(u_j), \ j \in J \}$. The following sequence of inequalities establishes the claim of Proposition 4.4:

$$
\left\| \sum_{j=1}^{N} \lambda(u_j)h(u_j) \right\|_{L_2(\Pi)} \geq \left\| \sum_{j \in J_0 \cup J_1} \lambda(u_j)h(u_j) \right\|_{L_2(\Pi)}
$$

$$
= \left\| \sum_{j \in J_0 \cup J_1} \lambda(u_j)h(u_j) \right\|_{L_2(\Pi)} - \frac{\rho_d}{1 - \delta_{2d}} \sum_{k \geq 2} \|\lambda(k)\|_2 \sup_{v \in L_{J_0 \cup J_1}, \|v\|_{L_2(\Pi)} = 1} \|v\|_2
$$

$$
\geq \left( 1 - \delta_{3d} \frac{b}{(1 - \delta_{2d})^2} \right) \left( 1 - \delta_{2d} \right) \sqrt{\sum_{j \in J_0} \lambda^2(u_j)},
$$

hence $\beta_2^{(b)}(J) \leq (1 - \delta_{2d})/(1 - \delta_{2d}^2 - b\delta_{3d})$.

It remains to show that $\delta_{3d} < 1/(2 + b)$ is sufficient for $\beta_2^{(b)} < \infty$. Since $\delta_{2d} \leq \delta_{3d}$, it is enough to show that $\delta_{3d} < 1/(2 + b)$ implies $(1 - \delta_{3d})^2 - b\delta_{3d} > 0$. The latter is satisfied whenever $\delta_{3d} < \frac{2 + \sqrt{4 + 4b^2}}{2b}$. The elementary inequality $\sqrt{1 - x} \leq 1 - x/2, x \in [0,1]$, gives $\frac{2 + \sqrt{4 + 4b^2}}{2b} (1 - \sqrt{1 - 4/(2 + b)^2}) \geq 1/(2 + b)$, and the result follows.
